the micro-organisms. Balancing minerals are added to this, chiefly of a potassic and phosphatic nature, as well as pure cultures of nitrifying organisms, so that the finished, mixed product contains about 3 per cent of  $\text{NH}_4$ , 0.5 to 1.25 per cent of  $\text{P}_2\text{O}_5$ , and one-half to one per cent of  $\text{K}_2\text{O}$ . The organic matter is 75 to 80 per cent. The bacterial count is from 50,000,000 to 300,000,000 per gram, which increases with time. A bacterial count of 18,000,000 per gram in soil is remarkably high. This is a balanced fertilizer of unusual bacterial activity. It is employed by market gardeners and landscape architects rather than by farmers. The manufacturers claim for it a fertilizer value of several times its weight in stable manure and that one ton represents

ONIONS AS THEY GROW AT GREAT MEADOWS

the value of many acres of clover turned under and decayed to restore worn-out soil.

#### ORGANIC FIXATION OF FREE NITROGEN

The third product is called "inoculant" and is prepared by adding first to sun-dried humus various chemicals which render it more available for the growth of bacteria, much as bakers use yeast food in their dough. The inoculant contains ammonifying organisms which decompose the humus and render it more soluble, azotobacter, which live in all soils on the organic matter found in them, and radicicola, which cause the nodules to grow on the roots of leguminosae. Without radicicola

leguminous plants do not form nodules and without nodules they extract only fixed nitrogen from the soil and do not fix free nitrogen. In the described form the inoculant is composted for one year during which time the micro-organisms increase. Then there are added pure cultures of some 28 leguminous bacteria. Of these there are seven main types, of which some will answer for several species while others will answer for only one. Thus that which will inoculate alfalfa will also inoculate sweet clover, and the vetch bacteria will also inoculate garden peas. On the other hand, that which is good for soy beans is not active with anything else, and the same may be said of the bacteria for cow peas.

TIMOTHY WITH AND WITHOUT ENCOURAGEMENT FROM PREPARED HUMUS

To make sure to cover the largest variety of leguminosae, all 28 are put in. Finally there are added five different strains of azotobacter that are valuable in any soil that contains a good supply of organic matter. All of these micro-organisms live, so to speak, on good terms with each other; indeed, each appears to thrive better in the presence of the others.

Here we lose interest in standardized chemical analyses of the product. Two pounds of it are enough to inoculate an acre of land. It is in growing use by farmers, for leguminous crops. A favorite method is to mix one-half of the inoculant needed thoroughly with the seed, before sowing, and to scatter the remainder mixed with dry earth over the soil. Another method is to use it in composting manure heaps. One pound of inoculant, if six months time is allowed for composting, is enough to inoculate one ton of stable manure. The desired organisms do not generate spontaneously in manure; and the lack of them is often the cause of a farmer's bad luck despite heavy fertilizing. The proper use of inoculant seems to point the way toward biological as well as chemical control of fertilizer, which has long been greatly desired. It will be a great day for agriculture when every farmer works with a microscope.

## War Problems of the Rubber Industry

**How United States Manufacturers Met the Rubber Shortage and Devised Substitutes for Colors and Fillers—Real Triumphs in Making Gas Masks and Balloons—Making of Pleasure Vehicle Tires May be Discontinued**

By ANDREW H. KING

IN COMMON with all other industries, rubber has been called upon to bear additional burdens and to accept new responsibilities because of the war. Undoubtedly the most serious question which is confronting American manufacturers today is the shortage of rubber. When the embargo was first applied by the War Trade Board, factories were allowed seven-sixteenths of their last year's consumption. Ocean tonnage is now in even greater demand than it was a few months ago. As a consequence the ration has been cut to six-sixteenths, or three-eighths of last year's consumption. To meet this situation the manufacturers have agreed to restrict the production of pneumatic tires, tubes, tires for horse-drawn vehicles and non-essentials such as bathing caps, rubber bands, toy balloons, advertising specialties etc. The curtailment is now proposed only for the months of August and September, but it is not unlikely that even more stringent restrictions will be applied and that in the near future the manufacture of tires for pleasure vehicles will be entirely discontinued for the period of the war. The rubber industry is getting over to a war basis. The manufacture of everything that will help win is going steadily forward. Non-essentials are even now in growing disrepute.

Apparently the government has placed every privately owned car, whether Packard or Ford, in the non-essential class. In many instances this is wrong, since the machines furnish transportation to many suburbanites who are thus enabled to live in the country and work in the cities. The curtailment of tires will, no doubt, effect quite a saving in gasoline, but it seems that this desideratum might have been effected easier by licensing owners of cars and restricting their machines to purely business or war-industry purposes.

### IMPORTANCE OF TRUCK SERVICE

Truck tires are now in great demand. The value of motor-truck service can hardly be estimated, but it is enough to say that 400,000 new trucks will be placed in operation this year. In every war, transportation has always been the knotty problem. If we had had to depend on the railroads we would not have a single soldier in France today. Between all important cities trains of motor trucks now go back and forth. The railroads put the canals out of business because of superior speed. Truck trains now carry material from Detroit to New York much quicker than the express companies. Whenever anything must be had in a hurry they send a truck after it. Today the trucks are the red blood corpuscles of our defense. Every new machine must have at least four new tires, so on the basis of the above estimate 1,600,000 solid

tires must be provided this year. This figure is low, because many machines are equipped with duals on the rear wheels, making six tires to a truck. These truck tires take a lot of rubber. Of course compounds vary but a 34 x 6-in. solid tire will contain from 20 to 30 pounds of good rubber. It is readily apparent that the increase in solid tire production will more than offset the pneumatic tire curtailment, and it is not improbable that in another year the consumption of crude rubber will exceed the 160,000 tons used in 1917. Many of the new trucks will be owned by the Government but business men are buying them in large numbers. The problem the rubber men must solve is where to get rubber enough to keep the trucks moving. Without tires transportation would be in a hopeless muddle.

There is now no such shortage of raw materials as was in evidence at the beginning of the world war in 1914. Practically all compounding ingredients are produced in large quantities in this country. One of the first to show the effects of war demands was zinc oxide. In 1915-16 it advanced to about double its old price. About this time gas black was introduced. By 1916 there were at least six standard grades of black tires offered. Since then gas black has been recognized as an excellent substitute for zinc oxide and the resulting tire is admitted to be superior in many ways to the old. It has been estimated that fully 30,000,000 pounds of gas black will be used by the rubber industry this year.

### SUBSTITUTES FOR COMPOUNDING INGREDIENTS

Another ingredient which caused us no little worry in 1915 was antimony sulphide, which was formerly imported extensively from England and used in rather large quantities in the manufacture of inner tubes. The grades chiefly employed were known as golden and crimson antimonies. They consisted of mixtures of antimony tri- and penta-sulphides in varying proportions, and carried an added free sulphur content approximating 15 per cent. Certain varieties also carried calcium sulphate which was thought to intensify the color. With the beginning of the war, England found need for all the antimony she could produce, so our tube manufacturers had to do without. Many of them developed tubes equally as good as their old products without the least trace of antimony in them. Because of the high regard in which the public held red inner tubes, certain manufacturers colored their products with iron oxide but the larger number sold their tubes on their own merits. By the close of 1915 American-made antimonies began to come on the market and now the old-fashioned tube maker can make just as good a tube as he ever did, but with American antimony,

However, certain other manufacturers liked their new tubes so well that they have not changed them back to the old formulas. The reason for this is not due to any lack of quality in American antimony, but because of some very desirable properties of the new tubes.

Pigments at first gave us considerable trouble. The colors used by the rubber manufacturers are very simple, notably white, black, red, yellow, green, blue, and orange. The white is secured by zinc oxide, lithophone, whiting etc. Because of the extensive use of lithophone in both paints and this industry, a number of new plants for its manufacture have been erected. At the present writing the home demand has been satisfied. Black is the easiest color obtained; the various grades of lamp and gas black are all made at home. The chief red pigment is red iron oxide. It is extensively employed in coloring all sorts of articles. In the old days vermilion, mercury sulphide, was thought to be much better, but it is now recognized as being too expensive and much too heavy. Very pretty shades were obtained by its use, but because of its high specific gravity and the excellence of iron oxide colors it will never be extensively employed again. The yellows and oranges are produced by the different chrome pigments and ochres. At one time considerable arsenic yellow (sulphide) was employed. All these were obtainable in this country. The greens used are the well-known chrome products. There was at first some difficulty in obtaining ultramarine blue but American manufacturers are now producing a satisfactory color. Pigments for the rubber industry must be quite stable and must bear heating with sulphur without any darkening in color or decomposition.

#### DOMESTIC FILLERS AND ACCELERATORS

Barytes is one of the commonest fillers. It is extensively employed in mechanical goods and in certain high-class compounds, notably frictions. With the beginning of the war we found ourselves cut off from foreign sources of supply. Later the Southern deposits were opened and now there are three grades of domestic products obtainable: (1) An off-color barytes carrying iron which has been finely ground. It is applicable in dark colored products. (2) A white product (ground) from which the iron has been removed by acids. (3) A very fine white precipitated barytes which is much better than the ground product.

Both precipitated barium sulphate and carbonate have been proposed as zinc oxide substitutes. While not as satisfactory as zinc oxide their use in limited amounts is becoming quite general.

The great development in organic accelerators has come about since 1914, so the German dye industries got no chance to control it. At first each company made its own accelerators but now the American dye factories are producing thiocarbonyl, para-phenylenediamine, hexamethylene-tetramine etc. which are quite satisfactory.

There have been some rumors of a shortage in sulphur, but it is believed that with a little conservation our Louisiana supply will be found quite ample. Should the rubber industry ever be put to it for sulphur we may expect some stormy days ahead.

Instances could be multiplied without number where American ingenuity has found the loophole from a try-

ing situation by either finding a way to do without a certain material or by producing it at home. The real triumphs of our rubber manufacturers are not that they kept running full blast in the face of unusual conditions but that when called upon for war products they responded so well. I refer particularly to gas masks. They were expected to furnish all kinds of tires, tubes, and mechanicals as a matter of course, but the gas mask was something entirely new. The gases met with are exceedingly reactive. That rubber was compounded to resist them was indeed a victory. True, the British and French were pioneers, but the American masks are very good if not better than the best our Allies have so far produced. Without gas masks for our soldiers, the Huns would have won this war long ago.

The manufacture of kite and dirigible balloons is another instance. Hydrogen diffuses very readily through ordinary proofed fabrics. It has been necessary to develop new combinations which give maximum resistance. In this field the English and Scottish firms long held full sway. Thanks to their help, American blimps are now equal to those of our Allies.

The rubber industry is mobilized. Everything possible to aid in winning the war will be carried forward. Drags and unnecessaries may expect to be ditched.

#### Soap Substitutes in Germany

In view of the shortage of fats, attention in Germany is being directed to the use of the natural soap substitutes occurring in certain plants. Thus, the soapwort (*Saponaria officinalis*) contains large quantities of saponin, a fact which can easily be demonstrated by rubbing the leaves or stem in water when a thick soap lather is readily produced. The root is the part of the plant richest in saponin. After digging up, it is thoroughly washed, dried and reduced to as fine a powder as possible. It can then be used, both alone for the hands, and in conjunction with soda for linen. The substance is an excellent detergent with good lathering properties.

A number of other plants can be used for the same purpose, although their saponin content is lower than that of the soapwort. All these are common plants, easily gathered, and in many cases can entirely supplant the costly substance, soap.—(*Seifenfabrikant*.)

#### Utilization of Reclaimed Rubber in Germany

At the twenty-fourth general meeting of the German Bunsen Society (for applied physical chemistry) held in Berlin on April 8 to 10, 1918, Prof. M. Le Blanc of Leipzig exhibited specimens of a reclaimed rubber named "Agatit," the process of manufacture of which was worked out by him in collaboration with Dr. Lüttke. The material is being made in large quantities both in the solid form and as a fine emulsion. Its use is specified by the Reichsmarineamt in place of natural rubber for the preparation of sheeting and high-pressure packing material such as is used in submarine construction. It is also used as a substitute for leather; it can be nailed or sewn, it withstands sterilisation well, and the difficulty of rapid ageing has been overcome. Such articles as operating gloves (2mk. 50), finger stalls, and teats (0.25 mk.) are on the market.—(*Chem.-Zeit.*)

## Carbonization of Coal

**Rapid Advances Being Made in Coal Distillation Field—Semi-Coke and Carbocoal With Accompanying High Yields of Tars Rich in Oils**

By WALLACE SAVAGE

THE phenomenon of coal carbonization involves highly complex chemical reactions in three phases—the solid fixed carbon, or coke; liquid products, water and tar; and gas. The yield and character of these products vary widely with the nature of the coal and the physical conditions of temperature, pressure, time and contact surfaces. In commercial practice, it is known that practically none of the final products are liberated as such from the coal. Secondary reactions among the primary products have been studied and are

tially unaltered; at 450 deg. F. decomposition into paraffin oils, gases and solid substances begins, the mass fuses, swells and loses weight, and if distillation is completed, a porous coal is left; at 750 deg. F. new gases and vapors are liberated accompanied by a marked increase in the volume of the mass and the development of a very porous cellular structure; at from 825 to 980 deg. F. the liberation of oils is more rapid and in one hour a 36 per cent volatile coal is reduced fifty per cent in volatility and the apparent specific gravity of the residue to

FIG. 1.—THE BY-PRODUCT COKE OVENS AT GARY, INDIANA; BEE HIVES AT BLOSSBERG, NEW MEXICO

known to follow well-known physical-chemical laws. However, the application of chemical statics and dynamics to coal carbonization does not offer a means of simplifying results because of the number of the components in such a system, the only certain factor known being the maximum heat—no average temperature or pressures being determinable. The process may be divided into stages: From 215 to 225 deg. F. the moisture is removed; from 300 to 400 deg. F., a slight superficial softening of the coal takes place and some gases are given off, but the character of the fuel is substan-

about 0.75; at very high temperatures—1500 to 3000 deg. F.—the volatile hydrocarbons are practically entirely removed and the carbon residue fused to great hardness.

In the manufacture of metallurgical coke, the beehive oven has yielded a satisfactory product from coals as high as 32 per cent in volatile matter, while with by-product ovens, the best results are obtained by utilizing harder coals of from 23 to 28 per cent volatile matter. Coals having above 4 per cent moisture content produce inferior results. During the past twelve years, the in-

stallation of by-product ovens in the United States has been phenomenal, practically doubling every four years. In Fig. 1, the story is told comparatively, the familiar bee-hive is hidden in a swarm of black tar condensates and smoke, while the Gary by-product coke plant is a strick observer of the anti-smoke laws. Now that our by-product coke production has about caught up with that of the bee-hive and we are soon to have about five million gallons of coke oven tar per week, a new source with a new type of tar looms into sight, that may revolutionize both our fuel and our coal oil industries.

#### LOW TEMPERATURE DISTILLATION SEMI-COKE

In 1890, Parker devised a process (Eng. Pat. No. 67) for producing a smokeless fuel by passing steam, water gas, or coal gas superheated to a temperature of 1100 to 1200 deg. F. through a mass of fused coal. The idea of using an inert gas as a heating medium did not give results and after years of investigation, Parker took out his famous Coalite Patent (Eng. Pat. 14,365, 1906) on externally heating coal in the presence of steam to

FIG. 2. BRIQUETTED SEMI-COKE AND FINISHED CARBOCOAL

around 800 deg. F. A number of retorts were tried, details of which are recorded in the English patent files from 1906 to 1911. The first proposal was to use the gas D-shaped retorts about 5 ft. wide, 7 ft. long and 16 in. high, the layer of coal being spread 6 in. thick. Coals with low melting points were distilled in tapering cylinders of about 11 to 12 in. in diameter, a gas outlet being connected with the usual tar recovery appliances. Since these proved unsuccessful, vertical retorts of flat oblong cross-section were tried, with no more success. Next a boiler tube system was installed, batteries of 4- to 6-in. pipes in a fire box being connected with the hydraulic main. These continued alterations in designs furnish an interesting commentary upon the persistence of the Coalite Company in trying to overcome their heating difficulties. The Coalite failures have not led to discouragement, for the work has been carried on in America and the goal apparently reached by the International Coal Products Company.

#### CARBONIZED SEMI-COKE BRIQUETS

In 1915, Charles Howard Smith<sup>1</sup> undertook to manufacture coke by an entirely new process. He proposed to get an intermediate soft 16 to 20 per cent volatile semi-coke, briquet it with hard pitch under high pressure, and carbonize at suitable temperatures. Fig. 2 shows the green and carbonized briquet product now being marketed under the name of "Carbocoal." This

fuel has been tested by several railroads and the U. S. Navy. It burns more freely than coke. With a rate of combustion of 27 lb. per sq.ft. of grate per hour, it evaporated 12.8 lb. of water per lb. of fuel; and with a 100-lb. combustion rate, 8.5 lb. of water. A maximum combustion rate of 166 lb. per sq.ft. of grate surface per hour has been reached. The air space is absolutely constant with this type of fuel. By adding certain minerals to the raw briquets, the melting point of the ash can be raised, so that the fusion of the ash to clinkers is prevented. There is no waste such as breeze etc., as all the accumulated fines are incorporated into the briquets. However, as previously indicated, the

FIG. 3. SEMI-COKE BRIQUETS

Falling from the Machine to a Belt Conveyor, Leading to the Carbocoal Retorts

Smith process is not confined to fuel manufacture, its main feature being in the production of 30 gal. of water-free tar per ton of 35 per cent volatile coal—an increase of from three to four times over ordinary tar yields.

#### SMITH PROCESS

In the Smith process, any grade of bituminous coal is reduced to about twelve mesh and fed continuously by a conveyor through a compound cylindrical retort having a double system of propelling paddle agitators mounted on two shafts. The retort is built of a refractory material of the carborundum type. The speed of the agitator is about four revolutions per hour, the design being such that the material is subjected to distillation for about one hour. The walls of the retort are heated to about 900 deg. F. externally by the combustion of the gas evolved in the process, checkerwork preheaters being installed below the fire box to make this possible. The retort discharges into an attached

<sup>1</sup>U. S. Pat. 1,177,727 and 1,224,424.

iron hopper, where the semi-coke cools off and is discharged at intervals on to a conveyor which carries it to

to the present time, only 4 or 5 per cent is left, this product burning freely in an open fireplace.

FIG. 4. INCLINED RETORT DURING CONSTRUCTION

a large crusher and Williams hammer mill where it is pulverized.

The finely divided semi-coke is mixed with several per cent of briquet pitch and thoroughly blunged in a direct steam-heated mixing machine. The hot pitched coke is fed into a briquetting machine of the roller type giving about two hundred and fifty briquets to the revolution. In Fig. 3 this machine is shown in operation. A conveyor carries the steaming green briquets to a hopper above the inclined retort feed doors. Fig. 4 shows an exposed retort during construction and Fig. 5 a group of retort ovens, the roofed structure at the left being a vertical Glover West retort, and the others being a single and a triple bank of 35-degree inclined retorts. The inclined retort has proved most satisfactory, the finished briquets discharging by gravity to a coke carriage in which they are quenched. The degree of carbonization in the inclined retorts could be carried to any predetermined extent, so that any amount of volatile matter can be left. Up

#### CONDENSING THE VOLATILES

In the low temperature retorting of the pulverized coal, the average contents of the retort are constant, because of the continuous feed. The evolution of gases is strongest at the discharge end, so that an additional outlet is connected with the gas main in conjunction with a central connection. A water seal is placed in the line at a considerably lower level than in gas practice, so that a shallower dip with a corresponding decrease in resistance to flow of gas and less back pressure in the retort is obtained. The hot gases are freed of solids and liquids as in ordinary gas practice. Table I indicates the main divisions of the products and their amounts.

TABLE I—PRODUCTS OF THE CARBOCOAL PROCESS

#### THE TAR AND ITS PRODUCTS

The tar obtained in the primary distillation of the coal has a specific gravity of 1 to 1.06, due to its large content of oils. A peculiarity of this tar is that it contains no naphthalene, anthracene or carbolic acid, but is rich in oils, tar acids and cresols which would indicate that the former are products formed from the

FIG. 5. EXPERIMENTAL RETORTS AT NEWARK, N. J.

latter under higher temperature conditions. Chart I gives a diagrammatic view of the coal tar industry and a partial list of the immense number of commercial products derived from it. From being an undesirable waste product, it is rapidly advancing to be an absolute necessity, with an unlimited consumption for its products.

In obtaining a high yield of benzol and toluol, the light condensates are passed through long, highly heated tubes, where the gas retort wall effect is reproduced.

### THE FUTURE OF COAL CARBONIZATION

A large, low-temperature coal distillation plant is now being built at Clinchfield, Virginia. The Government is backing the Smith process there with a view to getting coal-tar oils for the manufacture of explosives and a fuel for the Navy that is as flexible and smokeless in combustion as fuel oil. Carbocool is considered to have been sufficiently advanced beyond the experimental stage at the Newark plant to justify going into a larger

CHART I.—PRIMARY TAR FRACTIONS AND THEIR COMMERCIAL PRODUCTS

giving a large yield of pure aromatics. Table II gives the tar products produced per ton of coal. It will be noticed that an increase of the products in this process

over standard by-product coke-oven practice is mainly in the oils, the factors being: light oil, 6; middle oil, 8; cresote oil, 4; heavy oil, 9; and pitch, 2. Without subsequent cracking, there will be a considerable percentage of paraffin oils, but as the supplies of benzol etc. from other sources will soon be more than can be consumed in the chemical industries, these oils will probably be used direct as solvents and motor fuel. The pitch will be low in free carbon, so that if used by itself, it would have a rather high temperature susceptibility (i.e. soften rapidly with heat); however, it can be compounded with the coke oven tars to give very satisfactory products.

undertaking. If the final outcome is as anticipated, Carbocool will release vast amounts of petroleum fuel, will furnish great quantities of coal tar products, and if developed to its full possibilities, will aid immensely in giving our cities a clear sky line and an atmosphere unpolluted by tar. Mention might also be made that the saving in laundry soap might not be a negligible item in the economies effected.

Upon a brief survey of the possibilities presented in this coking process, the main items aside from the advantages of the refined carbocool are the demand for motor engine fuel, road tars and cresote oils. Undoubtedly, the prices of these commodities shall advance to a point commanding sufficient production to equal their requirements. The ten per cent consumption of raw material for fueling the process is not a large expenditure. The cost accountant probably will have no difficulty charging the major products alone with all the manufacturing costs. The waste of the beehive coke ovens has been spoken of on the platform and in the press for years. Now that great things have been accomplished with by-product coke ovens, the sequence is naturally to extend their scope. Should the results warrant the confidence now reasonably put in the Smith process, the extent to which the coal tar industry can grow is unbounded.

# The Metallography and Heat-Treatment of Metals Used in Aëroplane Construction—V

## Results of Tests to Determine the Best Brazing Materials and Fluxes—Strength of Brazed Joints—Beneficial Effect of Heat Treatment—Comparison of Brazed and Welded Joints

By F. GROTT'S

Chief Metallurgist Curtiss Aëroplane and Motor Corp.

### INVESTIGATION OF BRAZING MATERIALS

**T**HE object of this investigation was to determine (a) the best metal for making brazed joints between milled steel fittings, and (b) the best flux for the same. The materials used were various copper alloys and different fluxing materials.

Cold-drawn steel bars 8 in. long and  $\frac{1}{2}$  in. hexagon cross-section were butt-brazed, and the tensile strength of the joints taken. In a certain number of cases experiments were repeated with different fluxes; in others the brazed bars were subjected to heat-treatment. The brazing in a part of the series was done with an oxy-acetylene torch; in the other cases, with a fire produced by two gas blow-pipes so adjusted that the tips of the inner flame touched the metal.

In the first series of experiments joints were made with five different brazing metals by means of the acetylene torch, one each with a mixture of five parts boracic acid and one part borax mixed to a paste with water and applied wet to cold metal, and with zinc chloride similarly applied. The resulting tensile

| 1        | Wire 116-1     | 6,840            | 31,500      | 2,590               | 11,900      |
| 2        | Wire 116-2     | 6,410            | 29,500      | 3,070               | 14,100      |
| 3        | Wire 116-3     | 7,650            | 35,000      | 1,900               | 7,700       |
| 4        | Wire 116-4     | 6,760            | 31,000      | 3,170               | 14,400      |
| 5        | Wire 116-5     | 6,880            | 31,750      | 3,000               | 13,800      |

strengths are given in Table I. With zinc chloride the joints were only partially covered with braze, and the flow was very poor. Preliminary experiments with quartz sand, sodium carbonate, and a mixture of the two gave negative results.

The melting points and compositions of the five different samples of brazing wire are given in Table II.

TABLE II—MELTING POINTS AND COMPOSITION OF BRAZING METALS

| Wire  | Melting Point | Copper, Per Cent | Zinc, Per Cent | Tin, Per Cent | Iron, Impurities, Per Cent |
|-------|---------------|------------------|----------------|---------------|----------------------------|
| 116-1 | 1,590         | 56.76            | 42.18          | 0.45          | Trace                      |
| 116-2 | 1,610         | 60.18            | 39.07          |               | 0.65                       |
| 116-3 | 1,614         | 59.22            | 39.61          | 0.27          |                            |
| 116-4 | 1,603         | 66.52            | 32.78          |               | 0.70                       |
| 116-5 | 1,602         | 60.70            | 38.45          |               | 0.75                       |

Joints made by means of the acetylene torch, using the boric acid and borax mixture as flux, and various brazing metals, gave the results shown in Table III.

TABLE III—RESULTS OF BRAZING WITH VARIOUS METALS

| Exp. No. | Brazing Metal                | Load  | Lb. Sq. In. |

### CONCLUSIONS ON INVESTIGATION OF BRAZING MATERIALS

The joints brazed in the gas fire, using copper-zinc alloys with boric acid flux, nearly all exceeded the maximum strength of steel used.

Pure copper does not give as good results as alloys. It does not flow as well, and it is more difficult to produce a perfect joint with it.

With copper-zinc brazing alloys boric acid leaves little to be desired as a flux. It melts and flows freely, and dissolves the oxides readily. It is preferable to borax in that it is free from the frothing caused by the water of crystallization in commercial borax, and hence is easier to handle on the hot metal. It makes no difference how it is applied as long as a sufficient amount is fused on the joint to insure a complete cleaning of the metal.

### STRENGTH OF BRAZED JOINTS; EFFECT OF HEAT-TREATMENT

The object of the investigation was to determine (1) the relative strength of joints brazed with brazing metal of different compositions (a) brazed with acetylene torch, and (b) brazed in a gas fire; and (2) to determine the effect of heat-treating on joints brazed with torch and with gas fire.

(1) Bars of cold drawn  $\frac{1}{2}$ -in. hexagon steel were butt-brazed with different metals by the two methods of heating and the tensile strength of the joint taken.

(2) A series of bars as brazed, and one-half of them heat-treated by heating to 1600-1625 deg., quenching in oil and drawing at 900 deg., after which the tensile strength of the joints was taken.

**Preparation of Brazing Metal.** A brazing metal was made by melting together 6 lb. of copper and 1½ lb. of zinc under a borax flux, and allowing the melt to cool in the crucible. The ingot obtained was then sawed in two, and one of the halves remelted, and a bar made by pouring a portion into a mold. The ingot and the bar showed the following percentage composition by analysis:

|            | Copper | Zinc  | Iron  | Bismuth | Lead  |
|------------|--------|-------|-------|---------|-------|
| Ingot..... | 81.74  | 18.20 | 0.06  | Trace   | Trace |
| Bar.....   | 82.60  | 17.30 | Trace | Trace   | Trace |

The bar was used to make twelve joints each with the acetylene torch and the gas fire; and one-half of each of these sets was heat-treated.

The tensile strengths were then taken with results shown in Table VI. Increase in strength of torch braze,

of heat-treated over untreated: torch, 5234 lb. sq.in.; fire, 750 lb. sq.in.; per cent increase, torch 12 per cent., fire 0.2 per cent.

A metal was made by melting together 85 parts of copper and 15 parts zinc, remelting and ingot and casting a bar which analyzed 87 per cent copper and 12.4 per cent zinc. With this metal used in a fire braze on the hexagon rods, results were obtained as given in Table VIII. The results showed such inferiority that no further test was made with this metal.

TABLE VIII.—TESTS OF COPPER-ZINC BRAZING METAL

| Exp. No. | Load  | Lb. Sq. In. |
|----------|-------|-------------|
| 63       | 6,790 | 31,200      |

### CONCLUSIONS ON STRENGTH OF BRAZED JOINTS

Joints made with the acetylene torch were distinctly stronger than those made in the gas fire.

The brazing metal containing 83 per cent copper and 17 per cent zinc gave strongest joints.

Heat-treatment of the joints acetylene-brazed gave a marked increase in strength.

**Remarks.** The results obtained demonstrated that it is practical to make brazed joints that will be materially improved by heat-treating the steel after brazing. Brazing metal containing from 20 per cent to 15 per cent zinc has a sufficiently high melting-point to admit of heat-treatment and flows well in operation.

### INVESTIGATION OF BRAZED AND WELDED JOINTS

The object of this investigation was to determine the effects of heat-treatment on joints brazed with different brazing metals, and a comparison of the relative strength of brazed and acetylene-welded joints.

**Materials.** Cold-drawn seamless steel tubing, and brass and copper for brazing metal.

Sections of tubing were cut 6 in. long. These were respectively 1 in. and ½ in. outside diameter and both of 16 gage. The larger diameter pieces were cleaned out at one end by means of a reamer, and the ends of the smaller pieces were cleaned off by filing in the lathe. This preparation provided joints free from scale, and also permitted the smaller tube to telescope the larger with a free fit. Fifty pairs of these tubes were prepared, comprising five series of experiments of ten each:

- Dip-brazed, with standard brazing brass
- Gas-brazed, with standard brazing brass
- Oxyacetylene-brazed, with standard brazing brass
- Oxyacetylene-brazed, with pure copper
- Oxyacetylene-welded

One-half, i.e., 5 pairs of each series (except A, all of which were heat-treated by mistake) were heat-treated after brazing, by heating to 1600 deg., oil quenching, and drawing to 900 deg.

In each series a part of the joints were ⅜ in. length, i.e., the smaller tube telescoped the larger ⅜ in.; a portion were ½ in., and the remainder ¾ in.

Boric acid was used as the flux.

After the joints were made and heat-treated, the pieces were cleaned by sandblast and any fillets that had been formed were filed away.

Series B and C were brazed with the brass described in the previous report, containing 82.6 per cent copper and 17.3 per cent zinc, which is practically the composition of the government specification brazing metal. Series A was made with a metal not substantially different. A piece of copper tubing was used in Series D.

The completed pieces were subjected to test for tensile strength. The results are given in Tables X, XI, XII, XIII and XIV.

\* Joint pulled apart.

The 1/8-in. tubing alone, without any treatment, gave a yield point of 8,760, and ultimate strength of 9,550 pounds.

A pair of tubes, brazed with the acetylene torch, meeting but not telescoped, the joint consisting only of a

fillet flush with the larger tube gave a yield point of 7000 and ultimate strength of 10,390 lb., the smaller tube parting, leaving the joint intact.

#### CONCLUSIONS ON BRAZED AND WELDED JOINTS

(1) The best brazed joints, all points considered, were obtained with standard brazing metal, made with the acetylene torch and heat-treated. The joints showed (a) the highest average ultimate strength, (b) the highest minimum strength (c) the highest yield point, and (d) the smallest proportion pulling apart at the joint.

(2) The methods of brazing, considered with reference to the above points, ranked as follows: (a) acetylene torch, (b) dip, (c) gas fire.

(3) The best brazing metal was the standard brass.

(4) All welded joints were weaker than the ultimate strength of the tubing.

(5) The average strength of heat-treated brazed joints was 9.6 per cent higher than that of the untreated.

(6) In only one case did a brazed joint formed by a lap of 1/4 in. pull apart, and in that case the ultimate strength was over 11,000, which is considerably above the normal strength of the tubing.

*Remarks.* In the case of brazed joints made under the best conditions, as previously described, with steel that has been subject to cold-working, as drawn tubing or cold-rolled sheet, and untreated, the weakest part is the steel above the joint where it is subjected to the heat of the flame during the brazing process. The 100

per cent efficient brazed joint is therefore entirely practical, and could probably be substituted to advantage in many cases where welding is now practiced.

The superiority of brazing done by the acetylene torch over that done with a gas fire was referred to previously; further experiments confirm those conclusions.

The greater strength of the joints made by the acetylene torch are apparently due to a difference in the physical condition of the metal. Micrographs of joints made with the same metal by the two different methods of heating show marked variations in structure, that made with the acetylene torch having a very fine grain, while the other shows a coarse crystalline structure, as will be seen by reference to Figs. 97 and 98 respectively.

Analysis of the metal in joints made in the same series of experiments shows that the acetylene torch reduces the zinc content of the metal 6 per cent, while the gas fire reduces it only 2 per cent.

|                                              |        |      |
|----------------------------------------------|--------|------|
|                                              | Copper | Zinc |
| Composition of metal before brazing          | 82.6   | 17.3 |
| Composition of metal after acetylene-brazing | 88.8   | 11.2 |
| Composition of metal after gas fire-brazing  | 84.6   | 15.4 |

The difference in composition, however, does not account for the difference in strength; in fact, the reverse would be expected, since the strength of copper-zinc alloys normally decreases as the zinc content decreases through this range of proportions. Joints brazed with a metal of almost identical composition to the acetylene joint showed very inferior strength. (See experiments 63-68.) It seems probable that as a result of the conditions produced by the acetylene torch, beta crystals of copper-zinc solid solution are formed which remain after cooling. The fact that these joints show a pink color on fracture (Fig. 97), while the others have the pure yellow color of the alpha crystals (Fig. 98) tends to confirm this opinion. Whatever the cause, there is no doubt that the torch-brazed joints are stronger, and that their strength is further increased in the process of heat-treating the steel.

#### FURTHER INVESTIGATION OF BRAZING VS. WELDING

The object of this series of tests was to determine:

- (1) The relative strengths of brazed and welded joints;
- (2) the effect of heat-treating on brazed joints; and
- (3) the effect of heat-treatment on welded joints.

**Materials.** Strips of cold-rolled sheet steel, 7 in. x 0.925 x 0.1; brass containing 87 per cent copper; boric acid flux, and still wire for welding.

**Method.** Ten pairs of steel strips were butt-brazed with the acetylene torch, and ten pairs butt-welded, the work being done carefully by experienced workmen. One-half each of the brazed and welded bars were then given the prescribed heat-treatment for this grade of steel, viz.: heating to 1600 to 1625 deg., quenching in oil,

| in. 54,000           | ...       | 66,400   | ...     | 47,500   | ...       | 61,200   | ...     |
| * Steel bar faulted. |           |          |         |          |           |          |         |

and drawing at 900 deg. All the bars were then sand-blasted, and the joints carefully filed down to the dimensions of the bar, after which they were subjected to tests for tensile strength, with the results given in Table XV.

**Comparative Strengths Based on Averages.** Untreated brazed joint is 22.7 per cent stronger than untreated welded joint. See Figs. 99 and 101.

Treated brazed joint is 40 per cent stronger than untreated welded joint. See Figs. 100 and 101.

Treated brazed joint is 8.8 per cent stronger than treated welded joint. See Figs. 100 and 102.

**Effect of Heat-Treatment.** The treated brazed joint is 23.3 per cent stronger than the untreated joint. The treated welded joint is 28.8 per cent stronger than untreated joint.

**Comparative Strengths Based on Minimum Loads.** Untreated brazed joint is 19.2 per cent stronger than untreated welded joint.

Treated brazed joint is 55 per cent stronger than untreated welded joint.

Treated brazed joint is 7.8 per cent stronger than treated welded joint.

Treated brazed joint is 29.5 per cent stronger than untreated joint.

Treated welded joint is 42.3 per cent stronger than untreated joint.

Two out of five untreated brazed joints were stronger than the maximum strength of the steel.

One out of five welded joints was stronger than the maximum strength of the steel.

None of the treated joints were as strong as the steel, showing that heat-treatment strengthens the steel in a greater proportion than it does either the brazed or welded joint.

All of the brazed joints exceeded in strength the yield point of the untreated steel; all but one of the welded joints exceeded the yield point of the steel.

**Conclusions.** On every basis of comparison, in average, minimum, and maximum strength, the brazed joint proved stronger than the welded joint; and in both kinds of joints heat-treating produced a marked increase in strength.

**Remarks.** In these experiments the welding was done under the most favorable conditions for producing a good joint; the pieces were thin enough so that there was no difficulty in heating the joint up to welding temperature, and they were welded on both sides. The brazing conditions were hardly as favorable as the average.

The beneficial effect of heat-treatment of brazed joints confirms the results of former experiments, and leaves no room for doubt of the correctness of the conclusions.

Producer-gas tar or oil is washed with alcohol at a moderate temperature. Air is blown through, forming oxygenated products which are dissolved by the alcohol. The alcohol layer and the undissolved portion are separated and both freed from spirit. The oxygenated products are left as heavy viscous liquid suitable for lubricating wagon axles. The undissolved portions are lighter and can be fractionated into motor spirit and lubricating oil. The necessity for washing with sulphuric acid, with its attendant losses and inconveniences is avoided. D.R.P. 302,398.

# Aluminium and Its Light Alloys—IV

Binary and Ternary Alloys—Conditions Favorable for Casting—Effect of Pouring Temperature on Tensile Strength—Alloys for Rolling and Forging

By PAUL D. MERICA

A VERY comprehensive investigation of the mechanical properties of rolled, binary light alloys of aluminium was carried out in 1915 by Schirmeister (341).

Schirmeister rolled out several compositions of many binary alloys systems of aluminium and tested their hardness and tensile strength. His method of preparation for the alloys was the same for all series and was as follows:

About 900 grams of the alloy was melted in a small gas crucible furnace, poured into a chill mould to plates 25 mm. thick. These were rolled in a 30 hp. mill at the rate of 40 meters per minute. The plates were first reheated after casting to from 400 to 500 deg. C. and rolled with intermediate annealing, with reduction at each pass of from 1 to 3 mm. to a thickness of 4 mm. They were then annealed and rolled cold to from 1.3 to 1.5 mm. thickness. Only those alloys of which the melting point was very considerably lowered by the additions were rolled at lower temperatures or cold. Specimens cut from these sheets were then annealed at from 300 to 370 deg. in a muffle furnace, allowed to cool, and tested after several days.

His results are given in the Table XIV (pg. 588).

## 9. EQUILIBRIA, BINARY AND TERNARY

In Table XV are described the equilibria for binary systems of aluminium as far as they are known; references are given for binary and ternary systems.

It is observed that most metals form compounds with aluminium; the solubility of the aluminium rich compound in the solid aluminium is generally almost zero. The three prominent exceptions to this fact are zinc, copper, and magnesium.

The light alloys of aluminium with these metals contain only small quantities of the added metal, as with increasing amounts the alloy quickly becomes brittle.

Metallographically the light alloys are usually heterogeneous, with a ground mass of almost pure aluminium and crystals of the compound of aluminium with the added metal; these are hard, brittle and more resistant to corrosion than aluminium.

## 10. COMMERCIAL ALLOYS

From the practical standpoint of the relative value of the various alloys which have been studied, the re-

TABLE XV. EQUILIBRIUM DIAGRAMS OF ALUMINIUM ALLOYS

A, B, C..... Binary systems  
D..... Ternary systems

(A) A compound or compounds of the metal with aluminium are formed; the aluminium-rich compound forms a eutectic with aluminium.

| Alloy System                                                                                  | References (*)                                        | Composition of Aluminium-Rich Compound | Melting Point of Aluminium-Rich Compound                                         | Eutectic with Aluminium-Rich Compound | Solubility in Aluminium-Rich Compound | Compound Formed                                                                                                                                          |

sults of these investigations are summarized in a statement of the alloys which are in commercial use today. The industry has taken and developed further those alloys which the results of investigation have shown to be promising from the standpoint either of mechanical strength or of other special properties.

For casting alloys the aluminium-zinc-copper or the aluminium-copper alloys have been most largely used, whereas for forging and rolling, the alloy, duralumin, has hitherto held its own in the commercial field. The only serious rival which duralumin has today as a rolling and forging alloy of maximum mechanical

| 0 0                  | 16,300                            | 32                  | 31                        | Rolled at 100 to 150 deg. C., 8 m. per min. to 1.4 mm. These alloys may be rolled up to 6 per cent or more. Results show that there is no advantage in the addition of cadmium.                                                                                                                                                                                                                    | 0 5                  | 15,300                            | 41                  | 26                        | Rolled at 450 to 500 deg. C., 40 m. per min. to 1.4 mm. These alloys may be rolled up to 20 per cent of silicon. The author finds that the resistance to atmospheric corrosion of this series is fairly good in spite of the fact that it has been claimed that silicon causes a great corrodibility in aluminium. The author believes that an addition of silicon is of advantage and that from 5 to 7 per cent of silicon may be added for rolling and forging alloys. |    |

| 0 0                  | 13,500                            | 41                  | 26                        | Rolled at 500 deg. C., 8 m. per min. to 1.4 mm. Chromium can be added to aluminium in amounts as great as 5 or 6 per cent and can be rolled at 500 deg. up to a content of 4 per cent. Chromium does not seem to offer any advantages as an addition to aluminium although it might be used to harden it in amounts up to 1 per cent.                                                              | 0 0                  | 13,500                            | 41                  | 26                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. Only a few alloys were made of this series. Results show that tantalum cannot be considered as a technical utilizable constituent for aluminium alloys.                                                                                                                                                                                                                                                                 |    |

| 0 0                  | 14,900                            | 34                  | 29                        | Rolled at 450 to 500 deg. C., 8 m. per min. to 1.4 mm. These alloys may be rolled up to approximately 11 per cent of cobalt. Four per cent of cobalt is about the most favorable composition.                                                                                                                                                                                                      | 3 0                  | 15,600                            | 27                  | ..                        | Rolled cold, 40 m. per min. to 1.4 mm. Tin diminishes the ease of working aluminium at higher temperatures; it is possible to roll these alloys only cold. Tin is an undesirable addition to aluminium.                                                                                                                                                                                                                                                                  |    |
| 0 6                  | 15,500                            | 35                  | 32                        |                                                                                                                                                                                                                                                                                                                                                                                                    | 4 8                  | 15,600                            | 27                  | ..                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | .. |

| 0 0                  | 14,900                            | 34                  | 29                        | Rolled at 400 to 450 deg. C., 8 m. per min. to 1.4 mm. These alloys may be rolled hot up to 12 per cent of copper. The author considers 3 to 4 per cent of copper to be the most advantageous composition.                                                                                                                                                                                         | 1 6                  | 16,400                            | 30                  | 33                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. These two metals are quite readily alloyed, although a high pouring temperature is necessary. Up to 6 per cent of titanium the alloys of this series are readily rolled. The physical properties are not such that the alloys may be attributed any technical importance.                                                                                                                                               |    |

| 0 9                  | 14,900                            | 34                  | 29                        | Rolled at 450 to 500 deg. C., 8 m. per min. to 1.4 mm. These alloys may be rolled up to a composition of 12 per cent although it presents some difficulty to most of the alloys. The author considers that although the iron-aluminum alloys do not show properties which would make them of any utility, it is shown by his work that 2 or 3 per cent of iron in aluminium alloys is not harmful. | 2 1                  | 16,800                            | 27                  | 35                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. The ease of rolling hot is not unfavorably affected by tungsten, which can be added to aluminium alloy rolled up to 6 per cent. Tungsten does not seem to offer any advantages as an addition to aluminium.                                                                                                                                                                                                             |    |

| 0 0                  | 14,900                            | 34                  | ..                        | Rolled at 300 deg. C., 8 m. per min. to 1.4 mm. These alloys can be rolled hot quite readily up to 4 per cent or more; the addition of lead in small amounts is not of any value, at the same time it has no marked ill effect upon the properties.                                                                                                                                                | 0 0                  | 13,500                            | 41                  | 26                        | Rolled at 350 to 400 deg. C., 8 m. per min. to 1.4 mm. Can be rolled up to 30 per cent; most suitable are from 12-14 per cent. These alloys can be rolled out up to 30 per cent of zinc. The author considers that the most suitable of them are those with from 12 to 14 per cent of zinc.                                                                                                                                                                              |    |

| 0 0                  | 14,900                            | 34                  | 29                        | Rolled at 450 deg. C., 8 m. per min. to 1.4 mm. It is possible to roll these alloys up to approximately 6 per cent. Above that the alloys crack and splinter. The author does not consider that magnesium is a valuable addition to aluminium for a rolling alloy.                                                                                                                                 | 1 3                  | 17,900                            | 24                  | ..                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. Manganese-aluminum alloys may be rolled to approximately 5 per cent without much tearing. The author considers that 1 or 2 per cent of manganese might be added with advantage to aluminium.                                                                                                                                                                                                                            |    |

| 0 6                  | 15,300                            | 33                  | 31                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. Manganese-aluminum alloys may be rolled to approximately 5 per cent without much tearing. The author considers that 1 or 2 per cent of manganese might be added with advantage to aluminium.                                                                                                                                                      | 0 0                  | 13,500                            | 41                  | 26                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. Zirconium acts much as does titanium as an alloy constituent of aluminium; alloys may be rolled up to 6 per cent of zirconium; do not show any remarkably good physical properties, however.                                                                                                                                                                                                                            |    |

| 0 0                  | 14,900                            | 34                  | 29                        | Rolled at 300 deg. C., 8 m. per min. to 1.4 mm. These alloys can be rolled hot quite readily up to 4 per cent or more; the addition of lead in small amounts is not of any value, at the same time it has no marked ill effect upon the properties.                                                                                                                                                | 0 0                  | 13,500                            | 41                  | 26                        | Rolled at 500 deg. C., 40 m. per min. to 1.4 mm. Zirconium acts much as does titanium as an alloy constituent of aluminium; alloys may be rolled up to 6 per cent of zirconium; do not show any remarkably good physical properties, however.                                                                                                                                                                                                                            |    |

(\*) The Brinell hardness numeral was determined with a 2.5 mm. ball, using a pressure of 62.5 kg.

(1) The Brinell hardness numeral was determined with a 2.5 mm. ball, using a pressure of 62.5 kg.

strength is one of aluminium-zinc-copper developed by Rosenhain & Archbutt (438).

CASTING AND DIE-CASTING

Pure aluminium is but rarely used in the cast form, owing to its softness, high shrinkage and poor machining qualities. Its alloys, however, with zinc, copper or magnesium or combinations of these are excellent and give with proper care very good castings.

In general the casting practice for aluminium alloys follows that for brasses and bronzes. The alloys may preferably be melted in ordinary graphite crucibles in either oil, gas, coke or coal furnace; care should be taken not to overheat the metal as it then oxidizes, absorbs gases and may at higher temperatures absorb carbon and silicon from the crucible. Good practice favors keeping the temperature of the metal during melting practically at its melting point by the continuous addition of solid metal. Pouring should be done at the lowest temperature at which the metal will completely fill the mold; a temperature of 700 deg. C. or below is satisfactory. A low pouring temperature is particularly important for aluminium castings because of the high specific heat of the metal; if poured at a high temperature the metal in cooling heats the mold so hot that the rate of cooling is very slow; a coarse grain and weak metal result.

No flux should be used in melting down, and the surface should not be covered with carbon, as this may be included in the casting. Just before pouring, however, a small amount of zinc chloride may be added with advantage. This thoroughly cleans the surface, and prevents dross from entering the casting.

In molding castings to be poured in aluminium alloy, two characteristics of the material should be borne in mind:

(1) The metal and its alloys are quite brittle or "hot short" and fragile at temperatures just below the melting point, and (2) they are light. Consideration of the first fact means that the mold or cores should not be too hard. Ordinary green sand, not too fine, is to be recommended and hard ramming is to be avoided. A large percentage of bad castings are probably due to non-adherence to this principle.

The mold should be poured carefully and not too rapidly as the metal may otherwise fail to fill finer parts of the mold. The casting should be stripped as soon as set in order to prevent cracking. Owing to the lightness of the alloys chaplets are rarely needed in anchoring cores.

Commercial casting alloys may be obtained in ingot form and it is perhaps in general best to use such material. If the metals are alloyed in the foundry, a hardener should first be made containing from 10 to 50 per cent of the alloying constituent. In melting down, this hardener is first melted and the aluminium then added.

For the usual alloys 0.156 in. per foot is accepted as the pattern-maker's allowance for shrinkage; for aluminium, this is 0.203 in. per foot.

*Re-melting of aluminium.* The re-melting of scrap aluminium alloy in coarse form offers no particular difficulty, but that of borings and chips is extremely difficult (Gillett, 306) owing to the fact that each particle

is covered with an extremely tenacious coating of  $Al_2O_3$ , which effectually prevents its coalescence with its neighbor. Two remelting methods are in commercial use. In one, the chips are puddled in iron pots until a pasty mass of metal accumulates, which is then heated to a red heat until the dross and dirt rises, leaving clear metal. In the other the chips are mixed with a chloride and fluoride flux and melted in a crucible until the metal collects at the bottom. In a modification of this method (McKinney, 306) a low melting point chloride-fluoride flux is melted down in a crucible and the aluminium chips fed into it; the oxide is fluxed off of the chips which melt and collect at the bottom.

By these methods from 50 to 95 per cent recovery of metal is accomplished depending on the cleanliness of the chips. The metal should not be used except for unimportant castings of which the mechanical properties are not a prime consideration. Chips of magnalium, remelted by a method described by Coulson (395) gave much lower tensile strength than the original virgin metal and practically no ductility; the use of a deoxidizer such as metallic calcium caused a partial recovery of the former mechanical properties.

A more recent development has been the practice of briquetting light scrap of aluminium alloy (Stillman, 299). Tests made showed a shorter melting time and a lower melting loss for remelted briquetted "aluminium" than for remelted chips (8.1 per cent as against 13.8 per cent melting loss).

*Effect of casting section and of pouring temperature on mechanical properties.* Gillett (316) has investigated the most important question of the effect of pouring temperature on the mechanical properties of aluminium alloy castings.

A heat of No. 12 alloy (see below) was poured at 703 deg. C. into test bars of different sizes. His test results are given in Table XVI. It is seen that the greater the cross section of the casting, the lower the resulting tensile strength.

In part B of the same table are given Gillett's results on the effect of pouring No. 12 alloy into a (S.A.E.) cast-to-size test bar (0.5 in. in diameter) in green sand from different temperatures. The hardness decreases with increasing pouring temperature. Gillett tested the effect of pouring temperature on 53 alloys in all

(see Table XVII) and concludes that in general the alloys are weaker by approximately 20 per cent when poured hot (1550-1600 deg. F.) than when poured cold (1225-1250 deg. F.). His results on the different alloys are given in Table XVII. An exception was noted in

by Carpenter and Edwards (380) who give the following results for chill castings of an alloy of 4.63 per cent copper, balance aluminium:

| Pouring Temperature, Deg. C. | Tensile Strength, Lb. per sq. in. | Elongation in 2 in., Per Cent |
|------------------------------|-----------------------------------|-------------------------------|
| 650                          | 21,700                            | 8.5                           |
| 724                          | 15,700                            | 5.5                           |
| 707                          | 10,900                            | 3.0                           |

TABLE XVII.  
EFFECT OF POURING TEMPERATURE ON THE TENSILE STRENGTH OF LIGHT ALUMINIUM ALLOYS.  
Gillett (316)

(The bars were presumably poured in the S.A.E. cast-to-size test bar, in green sand. Aluminium containing 0.3 per cent Fe and 0.2 per cent Si was used in the preparation of the alloys.)

the case of the 5 per cent magnalium and of the 2 per cent manganese alloy.

Rosenhain and Lantberry (466) have studied the effect of pouring temperature on the tensile properties of a chill cast aluminium-manganese-copper alloy No. 10 (see Table XIII) and find the following results:

| Pouring Temperature, Deg. C. | Tensile Strength, Lb. per Sq. In. | Elongation in 2 in., Per Cent |
|------------------------------|-----------------------------------|-------------------------------|
| 775-732                      | 12,900                            | 2                             |
| 687-675                      | 26,000                            | 8                             |
| 650                          | 25,300                            | 8                             |

Other tests have been made by Donaldson (438, discussion), who finds a falling off in tensile strength and elongation between 800 and 850 deg. C. for an alloy of 19 per cent zinc and 1 per cent copper:

| Pouring Temperature, Deg. C. | Tensile Strength, Lb. per Sq. In. | Elongation in 2 in., Per Cent |
|------------------------------|-----------------------------------|-------------------------------|
| 850                          | 20,400                            | 1.8                           |
| 800                          | 29,300                            | 4.0                           |
| 700                          | 22,000                            | 2.5                           |

and by Rosenhain (438, discussion), who contributes the following values for chill castings of an alloy of 20 per cent zinc and 1 per cent copper:

| Pouring Temperature, Deg. C. | Tensile Strength, Lb. per Sq. In. | Elongation in 2 in., Per Cent |
|------------------------------|-----------------------------------|-------------------------------|
| 850                          | 24,000                            | 2.5                           |
| 800                          | 30,800                            | 4.0                           |
| 750                          | 31,500                            | 3.0                           |
| 700                          | 31,700                            | 4.0                           |
| 650                          | 30,900                            | 5.0                           |

*Die-casting.* The term die-casting is rather vaguely understood to connote the casting of metal in metallic molds either with or without the mechanical application of pressure.

Die-castings may readily be made of aluminium alloys; the copper-aluminium alloys are particularly suitable for this class of work; aluminium-zinc alloys are difficult to handle because of their hot-shortness (Norton, 310). Norton describes the use by the Aluminium Castings Company of No. 12 alloy for this purpose. This metal gives castings which are of smooth surface, dense and dimensionally true within a very small margin ( $\pm .005$  in.). Mechanical properties for die-castings of No. 12 average:

|                                                                         | Sand Castings | Die Castings |
|-------------------------------------------------------------------------|---------------|--------------|
| Tensile strength, lb. per sq. in. ....                                  | 20,000        | 25,000       |
| Yield point (stress for 0.01 in. elong. in 2 in.), lb. per sq. in. .... | 13,000        | 13,000       |
| Elongation in 2 in., per cent .....                                     | 1.7           | 3.1          |
| Density .....                                                           | 2.84          | 2.87         |

Many articles are now die-cast in this alloy, such as parts of cash registers, typewriters, adding machines, and cooking utensils; pistons for gasoline motors are now produced of this alloy by die-casting.

Pack (302) describes an aluminium-copper alloy which is being commercially die-cast under pressure. The chief commercial difficulty with the die-casting of aluminium is the cracking or heat-checking of the iron or steel molds used; cracks appear in the mold after about 2,000 castings have been made in it.

*Composition and properties of casting alloys.* The physical properties of light casting alloys with which one is concerned are the tensile properties and the resistance to alternating stresses. The tensile properties of commercial alloys are of course well known; practically no data on the resistance to alternating stresses of these alloys are published although such data are of the utmost importance in view of the use of such castings for machine parts subject to vibration such as motor crank cases.

Some confusion exists with respect to the description of tensile properties; in this country a test specimen cast to size in green sand is usually used to determine these properties; this is usually 0.5 in. in diameter over the reduced section. In Great Britain a specimen cast to size in a chill is often used. Experience has shown that the tensile strength of chill test castings of light alloys will usually average from 3000 to 5000 lb. per sq. in. higher than for sand cast ones. This should always be borne in mind in comparing tests of these alloys.

Not only is the tensile strength of chill castings higher than that of sand castings, but also the elongation. In general any variation of casting condition which increases the tensile strength of a casting alloy increases also its ductility (elongation), and a double gain of hardness and toughness is thereby obtained.

Satisfactory results are obtained either on a cast-to-size test coupon, poured horizontally in sand with gate and riser, or with the Webbert type of cast-to-size coupon, cast in core sand and fed along its whole length by a gate and pouring head. The Naval Gun Factory (Washington) uses the latter form with a gate,  $\frac{3}{8}$  in. thick.

(1) "No. 12 alloy" (92 per cent aluminium, 8 per cent copper).

Melting range: 637 to 540 deg. C.

Shrinkage: 0.156 in. per foot.

Probably 95 per cent of all light alloy castings made in this country are of this alloy, probably the best known one to the trade. It is easily handled in the foundry, and does not suffer from hot shortness to the same degree that some of the other alloys do. This alloy can be depended on to give the following tensile properties when properly cast:

|                          |                        |
|--------------------------|------------------------|
| Tensile strength .....   | 18,000 lb. per sq. in. |
| Elongation in 2 in. .... | 1.5 per cent           |
| Specific gravity .....   | 2.89                   |

If the alloy is overheated or poured too hot, the tensile strength may be as low as 15,000 lb. per sq.in.; on the other hand with skillful handling in the foundry a greater hardness may be obtained, as high as tensile strengths of from 20,000 to 24,000 lb. per sq.in.

Jeffries<sup>1</sup> finds that this alloy when properly cast to give from 20,000 to 24,000 lb. per sq.in. tensile strength, will withstand 1,000,000 alternations of stress between 0 and 12,000 lb. per sq.in. tension without failure. The alloy is not as strong in impact test as No. 31 (see (3) below).

Broniewski (377) finds the electrical resistance of an alloy of this approximate composition to be 5.60 microhm-cm.

(2) Copper alloys containing from 8.5 to 14 per cent copper:

Melting range: 630—540 deg. C. (depending on copper content).

Shrinkage: 0.156 in. per foot.

These alloys are used for castings which are to be subjected to high temperatures such as manifolds, pistons, and also for castings to withstand pressure such as for pumps, etc.

The 8.5 to 11 per cent alloy is generally used for pistons and the 11 to 14 per cent alloy used for pressure castings.

These alloys will ordinarily give the following physical properties:

|                                 |                                  |
|---------------------------------|----------------------------------|
| Tensile strength .....          | 18,000 to 19,000 lb. per sq. in. |
| Elongation in 2 in. ....        | Usually less than 1 per cent.    |
| Density { 8.5—11 per cent ..... | 2.95                             |
| { 11—14 per cent .....          | 3.00                             |

Certain of the Lynite casting alloys manufactured by The Aluminum Castings Company are almost identical with the above Nos. 1 and 2. The composition and physical

properties of the Lynite alloys as guaranteed by the company are as follows<sup>2</sup>:

Lynite No. 146—for general castings, such as propellers, crank cases, etc.

|                      |                        |
|----------------------|------------------------|
| Copper .....         | 7.0—8.5 per cent.      |
| Other elements ..... | Not over 1.7 per cent. |
| Aluminium .....      | Balance.               |
| Density .....        | Not over 2.89.         |

Sand cast

|                          |                               |
|--------------------------|-------------------------------|
| Tensile strength .....   | 24,000—28,000 lb. per sq. in. |
| Elongation in 2 in. .... | 1.4 to 4.0 per cent.          |

Die cast

|                          |                              |
|--------------------------|------------------------------|
| Tensile strength .....   | About 28,000 lb. per sq. in. |
| Elongation in 2 in. .... |                              |

Lynite No. 122—for casting for use at higher temperatures: pistons, etc.

|                      |                         |
|----------------------|-------------------------|
| Copper .....         | 9.25 to 10.75 per cent. |
| Other elements ..... | Not over 2.0 per cent.  |
| Aluminium .....      | Balance.                |
| Density .....        | Not over 2.95.          |

Die cast

|                        |                              |
|------------------------|------------------------------|
| Tensile strength ..... | About 28,000 lb. per sq. in. |
|------------------------|------------------------------|

Lynite No. 109—for pressure castings.

|                      |                        |
|----------------------|------------------------|
| Copper .....         | 11.5 to 13.5 per cent. |
| Other elements ..... | Not over 1.7 per cent. |
| Aluminium .....      | Balance.               |
| Density .....        | Not over 2.97.         |

Sand cast

|                        |                        |
|------------------------|------------------------|
| Tensile strength ..... | 19,000 lb. per sq. in. |
| Elongation .....       |                        |

(3) "No. 31" (zinc 15 per cent, copper 3 per cent, aluminium 82 per cent).

Melting range: 625 to 440 deg. C.

Shrinkage: 0.156 in. per foot.

This alloy has hitherto been used more extensively abroad, particularly in Great Britain than here in this country. Its higher tensile strength as compared with No. 12 has not in this country outweighed the doubt in the minds of many of its performance and its freedom from deterioration upon aging. This illusion has now, it is believed, been largely dispelled and there seems no reason why the alloy should not become more popular.

This alloy can usually be depended on to give the following properties:

|                          |                               |
|--------------------------|-------------------------------|
| Tensile strength .....   | 22,000—25,000 lb. per sq. in. |
| Elongation in 2 in. .... | 0.5 to 3.0 per cent.          |
| Specific gravity .....   | 3.0                           |

When poured properly and at a low temperature a tensile strength of 30,000 lb. per sq.in. may be obtained with this alloy.

This alloy has a low resistance to alternating stresses, but is tougher in impact than the copper alloys (Nos. 1 and 2)<sup>3</sup>.

(4) Magnalium, 50 per cent alloy.

Melting range: 625 to 450 deg. C.

Shrinkage: 0.187 in. per foot.

This alloy is one of the earliest commercial alloys. The term originally connoting an alloy of aluminium containing from 5 to 30 per cent of magnesium, now covers a variety of commercial alloys containing magnesium and also small quantities of copper and nickel.

A "magnalium" used at one time by the Westinghouse Electric & Manufacturing Company (395) contains 5 per cent of magnesium. This alloy may be depended on to give the following tensile properties<sup>4</sup>:

|                          |                        |
|--------------------------|------------------------|
| Tensile strength .....   | 20,000 lb. per sq. in. |
| Elongation in 2 in. .... | 0.5—2.0 per cent.      |
| Specific gravity .....   | 2.63                   |

<sup>1</sup>Communication from The Aluminum Casting Co. through Prof. Z. Jeffries.

<sup>2</sup>Communication from Prof. Jeffries of The Aluminum Castings Co.

<sup>3</sup>Communication from M. J. I. Jones of the Westinghouse Co.

<sup>4</sup>Private communication from The Aluminum Castings Company, through Prof. Z. Jeffries.

With care a tensile strength of 25,000 lb. per sq.in. and an elongation of 5 per cent may be obtained.

(5) Alloy containing 35 per cent zinc.

Melting range: 585 to 440 deg. C.

Shrinkage: 0.156 in. per foot.

This alloy is much used for general castings in which strength is not a principal consideration. It casts well, but has little or no ductility. Its tensile strength is usually about 35,000 lb. per sq.in. as cast. Its specific gravity is 3.32.

(6) Alloy containing 1 to 2 per cent of copper and 1 per cent of manganese.

Melting range: 649 to 529 deg. C.

Shrinkage: 0.187 in. per foot.

This alloy is described by McKinney (453) and is suitable both for casting and for forging. Cupromanganese may be used in preparing it, and it is not apparently a difficult alloy to handle in the foundry. This alloy will usually have the following tensile properties or better:

Tensile strength .....18,000 lb. per sq. in.

Elongation in 2 in. .... 8 per cent.

Specific gravity .....about 2.80.

With care this alloy may be cast to have a tensile strength of 21,000 lb. per sq.in. with an elongation in 2 in. of 16 per cent. This alloy is used almost entirely by the Naval Gun Factory, Washington, D. C.

515

#### ROLLING AND FORGING

Alloys for rolling or forging generally contain smaller percentages of the "hardener" metal than those for casting. Except when zinc is used, the total content of added metal to such alloys rarely exceeds 6 per cent and is usually less. The rolling or forging of these alloys is usually carried out in a manner quite similar to the practice followed for aluminium, although the temperatures used for hot breaking down are often somewhat lower owing to the lower melting point of the alloy, and it is usually annealed during cold rolling.

(1) Aluminium-manganese alloy.

An alloy (No. 3-S) containing manganese is rolled by the Aluminum Co. of America particularly into sheet, for use wherever a stiffer material than aluminium is desired. This alloy is superior to most other alloys of aluminium in its resistance to corrosion. The tensile properties of this alloy in sheet form average:

|                                          | Hard   | Soft   |
|------------------------------------------|--------|--------|
| Tensile strength in lb. per sq. in. .... | 30,000 | 15,000 |
| Elongation in 2 in. per cent. ....       | 2      | 25     |

(2) Alloy containing 1 to 2 per cent copper and 1 per cent manganese.

This alloy, used at the Naval Gun Factory (453), for small forgings may be readily forged at a temperature of about 625 deg. C. If finished at a temperature of about 250 deg. C. the forging is much harder. Forgings of this alloy give the following tensile properties:

|                                          | Finished cold | Finished hot |
|------------------------------------------|---------------|--------------|
| Tensile strength in lb. per sq. in. .... | 27,800        | 21,100       |
| Yield point in lb. per sq. in. ....      | 27,800 (?)    | 12,200       |
| Elongation in 2 in. per cent. ....       | 12            | 27           |
| Reduction of area, per cent. ....        | 47            | 49           |

The alloy is said to be quite satisfactorily resistant to corrosion in sea air.

(3) A forging alloy used by the Aluminum Castings Company has the following chemical composition:

Copper, 2.75 to 3.25 per cent; aluminium, the balance.

It will yield the following tensile properties:

Tensile strength .....24,000 lb. per sq. in.

Yield point .....16,000 to 17,000 lb. per sq. in.

Elongation in 2 in. ....not under 3.5 per cent.

(4) A machining rod alloy (No. 15-S) containing zinc and copper is produced by the Aluminum Co. of America. The average properties are:

Tensile strength .....42,000 lb. per sq. in.

Elongation in 2 in. .... 10 per cent.

(5) The Aluminum Co. of America recommends an alloy of from 10 to 15 per cent zinc for general forgings. This is said to flow well in the dies, and has satisfactory physical properties.

Iron, Carbon and Phosphorus.—DR. J. E. STEAD added another paper to his contributions on the behavior of phosphorus in iron and steel at the annual meeting of the Iron and Steel Institute held in London, May, 1918, in which he recounted a series of experiments showing qualitatively that the temperature where the phosphide of iron ( $\text{Fe}_3\text{P}$ ) passed into solid solution in ferrite varied with the amount present, thus conforming to the expected behavior of a binary system such as salt-water. In 1890 he noted that slow cooling from 1200 deg. C. of a 12-point steel containing 2 per cent phosphorus gave free phosphide along ferrite cleavages. Experimenting now with a decarburized blast furnace "bear" containing free phosphide envelopes and inclusions in ferrite crystals containing possibly 0.5 per cent P in solid solution he found that the free phosphide entered the solution at some temperature between 800 and 850 deg. C., and was nearly complete after 15 minutes at 960 deg. Diffusion is very slow, and on reheating at lower temperatures the phosphide re-crystallizes around the traces of the original crystals. Free crystals of iron-nickel phosphide (rhabdite) contained in a meteorite commenced to dissolve after 12 hours at 600 deg. C. Alloys containing 2 per cent phosphorus made by the thermit process showed solid solutions after 6 hours at 1000 deg., but developed new crystals freely after 6 hours at 800 deg. C. A rolled bar which had previously been phosphized at a white heat was bedded in mill scale, and one end heated to 961 deg. C. for 60 hours. Phosphide crystals appeared in that portion which had been held at a temperature of 660 up to 900 deg., increasing in size with the temperature. In absolute amount they were maximum at 800 to 850 deg. C., while at 961 deg. a homogeneous solid solution existed. No eutectic films were shown, and no phosphide crystals were present in decarburized eutectoid zones, since phosphide and carbide are mutually repellant. Pearlitic areas in phosphoretic steel castings and the ferrite immediately adjacent are nearly phosphorous-free, while the body of the ferrite crystals contain the phosphide in solid solution. In the cementation of phosphoretic steel, the migrating carbon drives the phosphorus before it, eventually making localized spots of concentrated iron-iron phosphide solid solution. The specific amount of carbon absorbed therefore varies with the phosphorous content. At 1200 to 1300 deg. C. the concentrated  $\text{Fe-Fe}_3\text{P}$  solution melts at the center of the ferrite crystal in a globule, and on being further heated, eventually liquates as a ternary  $\text{Fe-P-C}$  eutectic.

## Personal

MR. G. A. ARMSTRONG has severed his connections with E. J. Loomis & Co., Philadelphia, Pa., to accept a position as chemical engineer in charge of intermediates with the Central Dyestuff and Chemical Co., Newark, N. J.

MR. W. J. ARMSTRONG, manager of the crushing and pulverizing sales department of the Jeffrey Manufacturing Company, Columbus, Ohio has recently received an appointment as captain in the United States Army and assigned to the Ordnance Department in Washington, D. C.

MR. ZENO D. BARNES is now connected with the general operating department of The Aluminum Castings Company, with headquarters in Cleveland. For the past three years Mr. Barnes was non-ferrous metallurgist for the Westinghouse Air Brake Co.

PROFESSOR GEORGE BORROWMAN has taken up research work for the Niagara Alkali Company under the direction of Dr. John E. Teeple, 50 East 41st Street, New York. He was formerly at the University of Nebraska.

MR. CYRIL B. CLARK of the Research Department of the General Chemical Company, New York, has been detailed on some special work for this company's Bay Point Works near San Francisco. Mr. Clark expects to return to New York in four months when the work is to be completed.

MR. JOHN A. COYE has accepted the position of assistant chemist with the General Chemical Company's Laurel Hill works.

MR. CONRAD DRESSLER has been awarded the John Scott medal by the Franklin Institute of Philadelphia in recognition of his contribution to the advancement of the science of firing (furnaces for annealing, etc.).

CAPTAIN J. J. GAILLARD has assumed the position of district engineer in charge of the Atlanta office, Portland Cement Association, succeeding Mr. W. Jess Brown who resigned to accept a commission as captain in the Ordnance Department, U. S. Army. Captain Gaillard joined the forces of the Portland Cement Association January 1, 1918, and since that time has been doing general promotion and inspection work in the district covered by the Atlanta office of the association.

MR. CHARLES HENROTIN of Haileybury, Ont., is operating a fluorspar property near Madoc, Ont., and is shipping this product to the United States.

MR. C. A. NASH has accepted the position of research chemist with the Cutler-Hammer Manufacturing Company, of Milwaukee. Mr. Nash was formerly associate in chemistry at the University of Chicago.

MR. L. J. PLETCHER has withdrawn from teaching to enter the service of the Texas Refinery, Port Arthur, Texas as research chemist.

DR. J. H. RANSOM has been elected professor of chemistry and director of the chemical laboratories in Vanderbilt University, Nashville, Tenn. Dr. Ransom has been at Purdue University for the last eighteen years.

MR. CHARLES F. ROTH, one of the managers of the National Exposition of Chemical Industries and Secretary of the New York Section of the American Chemical Society is in the Personnel Section of the Chemical Warfare Service where he has charge of the census of chemists which is being taken by the War Department.

MR. L. DUANE SIMPKINS has accepted the position as chief metallurgical chemist and metallographer for the Peters Cartridge Co., Kings Mills, Ohio.

to get his supply, but his status in war production, that directs the allocation of the metals.

**Aluminium:**—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40 to 45c; sheet aluminium, 18ga. and heavier, 42c; powdered aluminium, 100 mesh, 70c.

**Antimony:**—The recent rise in antimony was but temporary, the price now being 14 to 14½c. for duty paid spot delivery.

**Chrome:**—Western production is now in slight excess of demand. The nominal quotation for 40 per cent ore is \$1.40 per unit, while 50 per cent ore is bringing \$1.70.

**Copper:**—The price of \$520 per ton for car load lots and 27.3c. per pound for small quantities is permanently fixed.

**Lead:**—The lead market is limited by selling restrictions. Producers must sell at a uniform and pre-arranged price. In car load lots at East St. Louis, the price is \$155 per ton. In New York, all speculative and traders' lead has disappeared. The Lead Committee apportions lead at 8.05c. to legitimate consumers.

**Manganese:**—The scale prices on page 629 of CHEMICAL & METALLURGICAL ENGINEERING, June 15, prevail; the highest price per unit being \$1.35.

**Zinc:**—Spelter continues to advance. East St. Louis is selling at \$183 to \$185 per ton in car lots; New York quotations are from 9.4 to 9.5c. per pound; sheet zinc 15c. and zinc dust (300 mesh) 16c. per pound in 1600-lb. casts.

**Silver:**—The Government price of \$1.01½ is hoped to promote production.

**Tin:**—The market is awaiting further development on the inter-Allied conference on tin. The War Industries Board will soon announce regulation prices and control the distribution of our \$0,000-ton allocation. Tin is priced at 80c. per pound nominally.

**Tungsten:**—The western producers of scheelite are reluctant in offering at \$25.50 per unit. High grade wolframite is bringing \$25. Off-grade ores vary from \$20 to \$24.

### The Iron and Steel Market

On September 23 the War Industries Board began holding a series of meetings with representatives of different branches of the iron and steel trade to consider two things: (1) Possibilities of increasing production of steel; (2) possibilities of conserving steel by reducing the amount converted into various finished products. The board had previously called upon all war activities to pare their estimates of steel required as much as possible. This work is dictated by the fact that the estimated requirements for the half year still total 23,000,000 net tons while the production can hardly materially exceed 19,000,000 tons. One finished steel product is not considered, except in a general way, by the War Industries Board, that being tin plate, which is under the jurisdiction of the Food Administration. Early last May the production and shipment of tin plate

## Current Market Reports

### The Non-Ferrous Metal Market

*Tuesday, Sept. 25.*—The metal markets are quiet, distribution being under Government control; varying monetary offerings can exert no influence on the market. It is no longer a question of what a certain manufacturer will give

was required to be confined to the filling of Government orders and the requirements of the perishable foods. Early in September, with the end of the canning season near at hand, an order was issued restricting by 30 per cent the manufacture of tin plate during the fourth quarter. While it had been expected that at the end of the canning season tin plate would be allowed to go to the non-perishable foods, and perhaps also to other lines of consumption, the Food Administration made no order, but undertook to meet, in order, representatives of the packers of the various non-perishable foods, for the purpose of limiting their consumption of tin plate. At this writing the tin plate trade is in expectation of receiving orders to cut its production by still more than the 30 per cent originally prescribed.

The outstanding feature of the present situation as to steel supplies is that all the news relates to efforts to conserve steel by reducing the amount consumed by various finishing operations. Excepting the one item of rails, there is no important activity which is specifically designated as requiring an increased supply of steel. From one viewpoint, the strenuous efforts being made to conserve steel would suggest that there is a great shortage, but from another viewpoint there is the opposite suggestion, that by conservation along various lines a considerable tonnage of steel may be released while there is no well defined additional use to which the steel would be put, excepting in the one case of rails. As to rails, the Railroad Administration has been calling for 60,000 tons a week and has been receiving 40,000 tons, which, in 85-pound rails, is enough to lay 300 miles of track per week, and there is a question whether labor can be provided for any greater activity than this. The American Expeditionary Force has been calling for large tonnages of rails, and it is desired to increase the rate of shipment, though by what weekly tonnage is not known. If there is a deficiency in rails it certainly does not amount to any large fraction of the much talked-of 4,000,000 ton deficiency in steel in general.

Thus the aspect of the great question, whether or not there is enough steel, continues to change. Late in 1917 many steel producers expected steel to become plentiful within a few months, through the peace consumption decreasing. The sharp curtailment in production during the winter caused a postponement of the time at which steel was expected to become plentiful, a not uncommon view being that steel might be plentiful in April. Just at the beginning of that month the Director of Steel Supply began a campaign to convince the steel makers that more war steel was required and during the next three months the distribution of the entire output of steel was taken over by the War Industries Board. Eventually the steel industry was convinced that direct war needs and essential commercial requirements would absorb the entire output, while the shortage of several million tons the War Industries Board insisted would occur in the second half of the year was considered quite seriously. After the lapse of three months of the half year, however, with no evidence of any large deficiency accumulated, some doubt is beginning to be felt.

#### OPERATING CONDITIONS

Shortage of labor is felt more or less throughout the iron and steel industry, but no such shortage as to interfere seriously with production. The bottle neck, so far as steel output is concerned, is the supply of pig iron. More steel could be made, with the same supply of labor, if there were more pig iron. The present supply of pig iron, however, would be adequate if there were at the same time a normal supply of scrap, but war time conditions cause the outcome of scrap to be much less than normal.

The supply of pig iron, again, is much below what would be expected of the blast furnaces in operation if they were given normal operating conditions. Since April 1 the rate of pig iron production has been between 40,000,000 and 41,000,000 tons a year. Various comparisons, of the output in 1916, with allowance for new furnaces completed since the beginning of that year, and of the number of furnaces lately in blast, indicate that under 1916 conditions the output of pig iron should be at the rate of at least 43,000,000

tons a year. The cause of the discrepancy has been earnestly sought and the common disposition among furnacemen is to attribute the discrepancy chiefly to the quality of coke available. This led the Fuel Administration several weeks ago to undertake a system of coke inspection, while at the same time, by speeches and otherwise, the miners are urged to mine cleaner coal and the operators to pay more attention to coke quality in general. One coke operator has been required to refund \$80,000 to customers, and another \$75,000, on account of inferior coke furnished in recent months, and in future coke not up to standard is to be penalized in price \$1 a ton. Analysis of the Geological Survey's weekly reports of coke production indicates that the quantity of coke being produced is sufficient. The rate is 61,000,000 net tons a year, about 47 per cent by-product and 53 per cent beach, with the by-product increasing nearly every week.

Pig iron production increased somewhat during September and still better output is expected in October, traditionally the best month of the year for furnace operations. Late in September the Brier Hill Steel Company, Youngstown, O., completed a new furnace, and if the report is correct that the furnace cost \$3,000,000 a new record has certainly been set in blast furnace construction. Unless after the war there is to be no reversion at all to pre-war conditions, a very heavy amortization charge is imperative against such new construction.

#### FOURTH QUARTER PRICES

In many branches of the iron and steel trade claims were made that in the adjustment of prices for the fourth quarter various advances should be made. These claims were formulated in rather elaborate manner, with many meetings of the interests involved. The outcome was an advance of 25 cents a ton in Lake Superior iron ore, intended to cover wage advances, as the 45-cent advance effective July 1 was absorbed almost entirely by the freight rate advance, and an intricate advance in pig-iron prices. Unfinished and finished steel prices were not altered.

The price of each grade of pig iron had been uniformly f.o.b. furnace. All basis prices were advanced \$1 a ton, except that for Bessemer iron. Tennessee and Virginia furnaces were removed from the furnace basis and placed on a Birmingham basis. Furnaces north of the Potomac River and east of the Allegheny Mountains were placed on a Pittsburgh basis. Thus in the case of foundry iron 1.75 to 2.25 per cent silicon, the Tennessee furnace formerly sold at a delivered price of \$33 plus freight from furnace to delivery point, but will now sell at \$34 plus freight from Birmingham to delivery point, the realized price being increased by \$1 plus the freight advantage. As further illustrative of the new price schedule, the New England consumer formerly patronized the furnace making the lowest delivered price, Buffalo, eastern Pennsylvania, Virginia and Alabama being more or less in competition. Now the prices made by the four districts will show wide variations, Buffalo selling at \$34 plus freight from Buffalo, eastern Pennsylvania at \$34 plus freight from Pittsburgh and Virginia and Alabama at \$34 plus freight from Birmingham. The consumer will choose when he can but will have to take iron from the furnace that can supply it. The arrangement is logical only in that it takes account that the costs have increased more in some districts than in others.

#### The Chemical Market

**COAL TAR PRODUCTS:**—Active trading has been more pronounced for the past two weeks in the majority of intermediates. However, activity in some of the items was curtailed by the scant supply of certain crudes and other unfavorable conditions that are prevailing. Prices on the whole are maintained at firm levels while some of the products have a strong upward tendency. Of these are benzol and phenol, which have attained a firmer position.

**Benzol:**—The actual trading position of this item has been rather erratic during the past two weeks, the latter period of which a firm situation developed with a fractional increase in price in tank car material and also that in drums. Stocks, however, are in liberal supply, but the demand is becoming more pronounced.

**Phenol:**—The market for this item has also developed a firmer tone. Its position, however, has been seemingly brought about by extensive purchasing for export purposes, while local requirements are reasonably active, in so far as the steady routine of business, which is generally passing. The firmness therefore having caused an increase in prices.

**Paranitraniline:**—The interest is persistent and the scarcity of stocks, which have been prevailing for some time, is at present offering no encouragement. The scattered spot lots which appear on the market are held at a variation of prices that trading is only as pressing requirements demand.

**Pora Amidophenol:**—The material is neither in pronounced demand nor supply. Prices continue at the same firm levels.

**Paranitrotoluol:**—Factors in this line are all sold up and the occasional lots which appear on the market are absorbed readily. Prices, however, remain at firm levels.

**Diethylaniline:**—Most producers are sold ahead for a fair period and supplies that are available are held mainly in second hands. The demand is steady and prices are quotably unchanged.

**Benzoate of Soda:**—A strengthening situation has become in evidence during the recent period with an advance in prices. It is the prevailing impression a higher market level will be seen, in view of the strong buying interest, more noticeable, however, for the acid material.

**Aniline Oil:**—The volume of business passing is apparently having no material effect on the quantity of stocks, though no unusual surplus is reported on hand. Prices are firm though, in some directions, fractionally easier.

**H-Acid:**—Spot lots are difficult to locate and producers are generally out of the market. Therefore prices are quotably nominal.

**Sulphuric Acid:**—Production continues to be confined to a few dealers. Prices are firm but the market is rather quiet, and supplies are in accordance with the consuming requirements.

**Toluol:**—The position of this material is no easier. It may be stated that only small quantities of the product are released by the Government, which has the entire situation in hand.

**Phthalic Anhydride:**—A strong demand with only limited stocks is the position of this item. Prices are without quotable change in view of the stringent situation.

**Metatoluylenediamine:**—The production of this material is not liberal, due to the toluol situation and, while the demand is only general, stocks are scarce. Quotations heard are still at firm levels.

**HEAVY CHEMICALS:**—The items that fall under this classification have in a number of instances commanded considerable interest in the past two weeks. Though many of the products which are in steady demand through routine channels have otherwise not been noticeably active and subject to no material change. Prices for the latter mentioned have undergone no particular fluctuations, though in some directions slightly lower levels were in evidence. Caustic soda, however, and its allied product, soda ash, were the prominent features of the market. Each of the items reaching levels, during the close, that were considered unusually high with no easement in sight and considerable speculation as to the futures. The supply of all acids continues scarce.

**Soda Ash:**—The volume of business in New York during the past two weeks has been exceedingly active. It may be safely stated that each day developed a more strengthening position, with prices increasing accordingly. The firmness coincident with the diminishing stocks made it appear as though the market was destined to unheard-of levels. Single bags were sold at from \$2.55 to \$2.60 warehouse, barrels from local store were generally held at \$3.15 minimum, and up to \$3.25. Double bags rolling to the coast were quoted at \$3.15 to \$3.20 and a car of dense ash rolling to the coast was held at \$5.15 coast.

**Sodium Cyanide:**—The item is more or less neglected in the open market and trading is mainly through routine channels. In the resale market spot lots were offered at from 31c. to 34c.

**Caustic Soda:**—The item during most of the past week has been exceedingly strong and to such an extent that stocks are diminishing in consequence of the pressing demand. On the spot prices ranged from \$4.30 to \$4.80, though the sale of the latter was generally regarded as high with the opinion that \$4.30 to \$4.35 represented the true market price for spot material. However, at these quotations offerings were scarce and material was held at such figures that large consumers displayed hesitancy in closing. Figures for over the balance of the year were \$4.35 f.o.b. works and for immediate shipment offerings were made at from \$4.35 to \$4.40 works, according to the seller.

**Pernmanganose of Potash:**—Production of this material under ordinary conditions has apparently been sufficient to take care of the consumption demand. But circumstances have created a sudden change during the latter end of the past week when a strengthening situation developed. Therefore in the open market sales have been reported at higher levels than were noted for some time and at the closing the U. S. P. material was generally held at from \$1.90 to \$2.00 with active trading at these figures, though in some directions the prices could be shaded. The technical product in sympathy with the U. S. P. has attained a firmer position and prices range from \$1.60 to \$1.75 according to quality and some of the higher grades are held at \$1.80.

**Bichromate of Soda:**—No unusual interest is evidenced for this material and it is difficult to determine its position in the market. Stocks are in liberal quantities and the entire situation is seemingly in favor of the buyer. Some low quotations are heard and sales are passing from 23c. to 24c.

**Bleaching Powder:**—Prices for this commodity have advanced in leaps and bounds during the interval and authorities in this line predict a 6c. market and perhaps higher prices in the near future. There seems to be a question at present writing, as to what the actual market level is. October-November-December were available at \$4.50 subject to government control, or requisition and some traders would not shade 4½c. for November or December. A report from the American Consulate-General, London, September 16, states:—

The Ministry of Munitions notifies that from September 16 no person shall produce or manufacture chlorine or chlorine compounds in quantities exceeding one-tenth per month under license, nor shall more than 10 be employed by manufacturer for purposes of other manufacturers, trades, and business except under license. From September 16 no person shall sell or offer for sale or purchase any liquid chlorine or bleaching powder exceeding following maximum prices: Liquid chlorine 6d, per pound, bleaching powder £15 per ton. However, maximum prices do not apply to goods for export from United Kingdom or sales of less than 56 pound weight.

**Carbon Bisulphide:**—In the situation of this material there is little change noted and trading is reasonably active. Prices remain firm in most instances at from 8 to 9c. f.o.b. works and 7½c. f.o.b. works, contract basis.

**Carbonate of Magnesia:**—The market has been barely steady with sellers offering various quotations and on the whole the item has been neglected by the majority of users. The technical is held at from 15 to 16c. ex store in bags of 100 lb. for less than carload lots and in larger quantities 14 to 15c. f.o.b. mills is the general asking price.

**Magnesia, Calcined:**—The high grade technical which is mainly in demand by the rubber making trade is an active item and is offered at 65 to 75c. medium grades, at 40 to 50c. and the heavy at from 9½ to 12c. Interest in the item is nothing of consequence, other than the regular routine of business.

**Bicarbonate of Soda:**—The present production of this material is reported to be insufficient to take care of all the business now placed. However, frequent lots appear on the market and two cars of this material for October-November delivery were quoted at \$3.10. The price is considered low as efforts to cover at \$3.25 were reported as unsuccessful. The market for prompt shipment is quoted by factors to be \$3.40 to \$3.50.

## General Chemicals

| WHOLESALE PRICES IN NEW YORK MARKET, SEPT. 24, 1918 |      |               |         |

## Plant Construction—Catalogs—New Publications

### Construction and Operation

#### Arizona

**KINGMAN.**—The Standard Mineral Co. will build a 50-ton flotation mill in the Mainard Mining District. Estimated cost, \$40,000. Ray L. Connell, engineer.

#### Arkansas

**MENA.**—The Baby Ray Mining Co., Room 11, Turner Building, Tulsa, Okla., is in the market for a steam shovel, log washer, belts, lumber, concrete, roofing, pumps and pipe. Estimated cost, \$25,000.

**ROGERS.**—Mr. George Pollard and Dr. Frank Schuckles will build a concentration plant and smelter for platinum and are in the market for engine, boilers, motors, pipe, pump, sludge and slime tables, crushers, lumber, concrete, belts, conveyors, tracks, ore cans, ore cars, smelter machinery or any, belts, lumber, steel sides and metal roofing. Estimated cost, \$80,000.

**ZELLVILLE.**—The Cowan-Banners Development Co. will build a 200-ton concentration plant, and is in the market for sludge and slime tables, crushers, air compressors, drills, ore cans, ore cars, belts, engine, boilers, lumber and concrete. Estimated cost, \$60,000.

#### Connecticut

**STRATFORD.**—The Raybester Co., 1427 Railroad Ave., Bridgeport, has awarded the contract for the erection of a one and one half story, 100 x 105 ft., brick and concrete factory, to J. R. Sheehan, 211 State St. Estimated cost, \$17,000.

#### Florida

**FORT LAUDERDALE.**—The city will install a water filtration plant. Address the Mayor.

**JACKSONVILLE.**—The Jacksonville Gas Co., Laura and Church St., received low bid for building a 2-story, steel gas plant, from H. Vesey, \$12,500.

**MOORE HAVEN.**—The Grass Fiber Paper Pulp Co., recently incorporated with \$150,000 capital, has leased 75,000 acres of saw-grass land and will build a plant to manufacture paper from saw-grass.

#### Illinois

**CHICAGO.**—The Union Stock Yards, 38 South Dearborn St., will build a 6-story, 32 x 70 ft. rear addition to its soap boiling building. J. H. Jilison, c/o owner, architect.

#### Indiana

**GARY.**—United States Government plans to purchase from 2000 to 3000 acres of land near here, on which to build an air nitrate plant.

#### Kansas

**BAXTER SPRINGS.**—The Miami Volunteer Mining Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, crushers, air compressors, conveyors, engine, boilers, lumber, roofing, etc. Estimated cost, \$65,000. J. L. Hawthorne, superintendent.

#### Louisiana

**MONROE.**—The city will build a filtration plant. Estimated cost, \$25,000. W. G. Kirkpatrick, Jackson, Miss., engineer.

#### Maryland

**BALTIMORE.**—The General Chemical Co., 1218-24 Munsey Building, has awarded the contract for the erection of a 3-story, 153 x 213 ft., concrete brick and steel chemical plant addition on Race and Winder St., to the Westinghouse, Church, Kerr & Co., 37 Wall St., New York City, N. Y. Estimated cost, \$155,000. J. M. Bellamy, manager.

**BALTIMORE.**—The Kennedy Foundry Co., Charles and Wells St., will build a concrete and brick addition to its plant, and is in the market for moulding machinery for the manufacture of mustard gas shells of semi-steel for the United States

Government. Total estimated cost, \$100,000.

**HAGERSTOWN.**—The Central Chemical Co., Thomas Building, has increased its capital stock from \$200,000 to \$600,000 and will build additions to its plant.

**INDIAN HEAD.**—The Bureau of Yards and Docks, Navy Department, Washington, D. C., received low bids for an oxidation absorption building, from the De Keni Construction Co., Dispatch Building, Union Hill, N. J., \$124,000; Austin Co., 1313 H. St., Washington, D. C., \$143,000; Chemica Construction Co., Tyron St., Charlotte, C., \$175,500.

#### Massachusetts

**SPRINGFIELD.**—The Hendee Manufacturing Co., 837 State St., has awarded the contract for the erection of a 1- and 2-story, 60 ft. pipe boiler plant and a 60 x 87 ft. hardening room, reinforced concrete, brick and steel, to E. J. Pinney, 264 Main St. Estimated cost, \$37,000.

#### Michigan

**GRAND RAPIDS.**—The Imperial Chemical Co., Ann St., will extend and improve its plant to provide for increased capacity.

#### Missouri

**GRANBY.**—Heaton & Hodges, Neosho, will build a 500-ton concentration plant and is in the market for two crushers, six sludge and slime tables, conveyors, air compressors, lumber, concrete, motors, engine, belts, pipe, roofing, bins, scales, cables, jigs, ore cans, ore cars and drills. Estimated cost, \$100,000. W. Heaton, superintendent.

**MACON.**—The city will build a sewage disposal plant, including Imhoff tank, sludge bed and storm overflow, involving about 790 lin. 18-in. sewer and straightening of creek channel. Frank L. Wynn, Syndicate Building, St. Louis, Mo., engineer.

**NEOSHO.**—The Neosho Mining Co. will build a 150-ton concentration plant near Spurgeon, and is in the market for crushers, boilers, engines, pipe, air compressors, concrete, lumber, roofing, conveyors, belts and wire cables. Estimated cost, \$340,000. C. Bushner, superintendent.

**ST. LOUIS.**—The LaCade Gas Light Co., 11th and Olive St., has awarded the contract for the erection of a 1-story, 200 x 1200 ft. steel plant for the manufacture of munition, to Austin Co., 1212 Euclid Ave., Cleveland, Ohio. Estimated cost, \$8,000,000. Noted Aug. 31.

**ST. LOUIS.**—The Pan Electric Manufacturing Co., 735 South 4th St., plans to build a 60 x 100 ft. administration building and laboratories. Estimated cost, \$50,000. W. C. Forder, in charge.

**ST. LOUIS.**—The R. & N. Kansas Limestone Co., Joplin, will build a 250-ton jig and concentration plant, and is in the market for four hand jigs, crushers, bins, pipe, lumber, cement, roofing, drills, engine, boilers, air compressors, belts, conveyors, car, track, cans and sludge tables. Estimated cost, \$65,000. W. A. Meese, superintendent.

#### New Hampshire

**NASHUA.**—The Nashua Manufacturing Co. has awarded the contract for the erection of a 5-story, 80 x 27 ft. reinforced concrete dye house, to the Turner Construction Co., 244 Madison Ave., New York City, N. Y.

#### New Jersey

**BLOOMFIELD.**—The International Arms & Fuse Co., Grove St. and Bloomfield Ave., will build a 1-story, 20 x 190 ft. heat treating shop addition to its existing works. Estimated cost, \$20,000.

**CAMDEN.**—The Dobbins Soap Manufacturing Co., Federal St., will build an addition to its plant and make alterations and improvements to its existing works. Estimated cost, \$20,000.

**CHROME.**—The American Agriculture Chemical Co. has awarded the contract for the erection of a 2-story, 101 x 227 ft. reinforced concrete fertilizer plant, to its Cable Works here, to the Turner Construction Co., 244 Madison Ave., New York City, N. Y.

**TRENTON.**—The M. M. S. Metal Co., Fall St., will rebuild its plant recently damaged by fire, entailing a loss of \$25,000.

#### New York

**BUFFALO.**—The Metal & Alloy Specialty Co., 25 Illinois St., will build a 2-story, 60 x 100 ft. brick and steel factory at Marion Ave. and New York Central Railroad. Elmer Rac, manager.

**CARTHAGE.**—The National Paper Co., 126 Canal St., will build a 3-story, 60 x 200 ft. concrete and brick paper mill. Estimated cost, \$60,000.

**ELIOT.**—The Hemington Arms Co. has awarded the contract for the erection of 2-story, 70 x 197 ft. dry kiln, to Richards & Co., 246 Elizabeth St., Utica. Estimated cost, \$35,000.

**NEW YORK CITY.**—The Goodyear Rubber Insulating Co., 105 East 131st St., will build a 2-story addition to its plant here.

**OSWEGO.**—The Hessler Foundry & Manufacturing Co., Mitchell St., will rebuild its plant which was recently destroyed by fire entailing a loss of \$100,000. The company manufactures brass and castings. C. J. Hessler, president.

**PIERMONT.**—The Piermont Paper Mills has awarded the contract for the erection of a 2-story, 100 x 250 ft. reinforced concrete structure, to Turner Construction Co., 244 Madison Ave., New York City, N. Y.

#### Ohio

**AKRON.**—The Kelly Springfield Tire Co., 229 West 57th St., New York City, N. Y., has awarded the contract for the erection of a 3-story, 40 x 130 ft. concrete, brick and steel rubber factory, to W. A. Franklin & Sons, 146 Howard St. Estimated cost, \$50,000.

**CLEVELAND.**—The National Carbon Co., West 117th St., has awarded the contract for the erection of six 1-story buildings, three 50 x 60 and three 60 x 80 ft. reinforced concrete, brick and steel, to the Hukin Conkey Co., Century Building. Estimated cost, \$100,000.

**CLEVELAND.**—The Ordnance Department, United States Government, Plymouth Building, Prospect and East 22nd St., will build a byproduct coke oven. Estimated cost, \$500,000.

**KINGS MILLS.**—The Peters Cartledge Co., 1700 Federal Bank Building, Cincinnati, will build a 2-story concrete brick and steel factory for the manufacture of munitions. Estimated cost, \$50,000.

**LORAIN.**—The Union Chemical Co., Union Building, Cleveland, has awarded the contract for the erection of eighteen, 1- and 2-story, reinforced-concrete, brick and steel chemical plants, to J. Hott & Co., C. Bushner, superintendent.

**MIDDLETOWN.**—The Paul Sorg Paper Co. has awarded the contract for the erection of a 2-story, 25 x 288 ft. brick, steel and reinforced concrete building, to Caldwell & Iseninger, 5th St. Estimated cost, \$60,000.

**ARDMORE.**—The Choctaw Refining Co., Carter Building, will build an oil refinery for the production of lubricating oil and wax, and will install oil refinery equipment etc. R. W. Wallace engineer.

#### Oklahoma

**DOUTHAT.**—The Suening Mining Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, crushers, conveyors, motors, lumber, roofing, concrete, engine, boilers, air compressors, pumps, pipes, cables and jigs. Estimated cost, \$65,000. J. Pulver, superintendent.

**DUNCAN.**—The city will build sewage disposal plant. Estimated cost, \$30,000.

**KANSAS.**—The Peabody Mining Co., Joplin, Mo., will build a 200-ton concentration plant and is in the market for crushers, sludge and slime tables, belts, cables, engine, boilers, air compressors, engines, lumber, concrete, ore cans and ore cars. Estimated cost, \$65,000. J. H. Wright superintendent.

**LINCOLNVILLE.**—The Lucky Pat Mining Co., Miami, will build a 200-ton concentration plant near here and is in the market for jigs, crushers, rolls, drills, air compressors, lumber, conveyors, engine, boilers, roofing, pumps, pipes, cables and slime tables. Estimated cost, \$65,000. J. Screener, superintendent.

**LINCOLNVILLE.**—The Nell Mining Co. will build a 400-ton concentration plant, and is in the market for lumber, roofing, crushers, slime and sludge tables, engine, boilers, motors, belts, drills, ore cans, ore car, wire cables. Estimated cost, \$40,000.

THE BOOTH-HALL COMPANY, Chicago, electric furnace builders and metallurgists, have moved their sales and administrative offices from 565 West Washington Boulevard to 2309 Archer Avenue, where only the engineering and construction departments have heretofore been located. By this change all departments of the business are combined and the furnaces in course of construction are at all times under the inspection of the officials of the company.

### The Fourth Liberty Loan and Victory

SIX weeks ago we hazarded the opinion that the Fourth Liberty loan would be a victory loan. Events since that time have only strengthened that opinion. There is danger, however, that optimism will lead to procrastination in seeing the fourth loan through to a successful finish in the allotted time. It should be realized that if peace came tomorrow we have governmental obligations for billions of dollars that would necessitate the flotation of the loan. Victory may be in sight, and we hope it is, but we feel it necessary to caution against lethargy in supporting the Government at this time. Germany's ninth tyranny loan is likely to fail in the face of the disaster confronting her arms, but nothing should be allowed to slacken our pace or weaken our purpose with victory in sight. Failure to "double the third" in the campaign period would strengthen the morale of the enemy and give him cause for renewed hope. It would weaken and discourage our own troops who would be utterly unable to comprehend such a failure in the light of their own accomplishments. We cannot afford to fail, and we are confident we will not; but we believe emphasis should be laid on the magnitude of the undertaking and the necessity of redoubled effort on the part of all if success is to be our reward. We want to be able to say that we fought while they fought, and that we kept at it as long as they did.

### A Reconstruction Commission Should Be Appointed Immediately

THE American Electrochemical Society is the first of the national scientific and engineering societies to consider formally the post-war future of the industry which it represents. Elsewhere in this issue will be found a comprehensive report of the symposium on electrochemical industry in the United States after the war, as presented and discussed at the recent meeting of the Society. It directs our attention to the great necessity which has existed for months past for a national movement to prepare for the reconstruction of our industrial organization and its readjustment to peace conditions. Some time ago CHEMICAL & METALLURGICAL ENGINEERING, in common with all McGraw-Hill engineering publications, proposed a commission to be appointed by the President, to devote its entire time and energies to the reconstruction problem. The subject was considered in detail, and the foundation was laid for the organization. There was no immediate response; but recently we have noted urgent appeals for national attention to the problem, and the introduction of several bills in Congress providing for commissions

to arrange for the transition of our industries.

The United States cannot act too soon. We have pointed out before that the other belligerent nations have long since had their commissions at work; that every other nation of importance has made more progress than we in formulating its problems and discovering their solution. We have been as slow to comprehend post-war conditions as we were to enter the conflict. But conditions in the two instances are different: there was someone to battle for us until we got our fighting clothes on, but there will be none to solve our problems when the conflict is over. Each nation will then be busy with its own affairs, and properly so.

There are two types of commission that can be created to study and handle the matter, one legislative and the other executive. We are unqualifiedly in favor of the latter. Legislative commissions are notoriously inefficient. They have a political cast and a political point of view. Their responsibility is indefinite, their qualifications doubtful. In legal talent they abound, but it is questionable whether they comprehend the problems of employment, production, distribution, and foreign and domestic commerce. A commission of executive appointment, on the other hand, could be created with a special view to its fitness for the great task. Leaders of industry and labor, economists and engineers, experts and specialists could be drafted by the President for such a commission. Its responsibility would be definite, its purpose unhampered by political considerations. Its findings would be guide-posts for industry. We understand that bills for both types of commission have been introduced in Congress. We express the hope that no legislative commission will ever be created, but that one of executive character will speedily come into being. The events of the past few days shows how near the end of the war may be; and the nearer the end, the farther we are from solving our problems.

## A Call to

### Save Paper

**P**ROBABLY one of the most thoughtless wastes in our daily life is the destruction of paper—newspaper and wrapping paper in the home, envelopes and writing paper at the office, magazines everywhere. Ordinarily this waste has passed unheeded, but today we look behind the product of the paper mill to the supplies needed for manufacture, and we visualize paper in terms of coal for power, caustic soda for pulp, chlorine for bleaching, and man-power for operation of the plant. All these commodities are needed for war service in the most direct manner, and consequently they are rationed to the paper industry. Paper, in turn, is rationed to those who buy from the mills. But it is a material of universal use, and its conservation becomes a duty incumbent on the most humble consumer. Methods of conservation are simple and obvious if we but stop and think. Ordinarily but one surface of a sheet of writing paper is used, and while we cannot endorse the universal practice of writing on both sides, we believe there is a big opportunity for saving there. Envelopes can be used for scratch paper, and large manila envelopes can be used over and over again by the simple expedient of pasting a new address over the old one. Waste paper of all kinds can be salvaged and sold to dealers.

## Deterioration of

### Reinforced Concrete

**S**OME time ago the U. S. Bureau of Standards reported the action of electric current on iron bars embedded in concrete. Layers of iron oxide formed at the anode with an accompanying expansion in volume of 220 per cent of the iron oxidized, which gave rise to a mechanical pressure sufficient to crack the concrete. At the cathode the concentration of sodium and potassium had a softening effect on the concrete, which became brittle and friable. Elsewhere in this issue, an excellent account is given of several cases of serious structural deterioration due to the corrosion of the reinforcing bars in the presence of salts. The origin of the electromotive force may be assigned to several causes but great differences in concentration of the electrolyte due to evaporation of the solution at the surface of the concrete may exert a considerable proportion of the potential. Exhaustive studies of this corrosion are being made. It is fundamental to modern engineering practice that means for overcoming it should be found at once. The domains of the chemical and civil engineers overlap here and it is incumbent on the former to use his most efficient research methods and find the solution of the problem.

Ordinary rust-proofing methods are not available except for a limited use of paint, which has certain serious defects. Less porous concrete can certainly be had by proper control of the batch mixes—the water content being the most abused. Allowance should also be made for actual drainage of the liquid portions from the aggregate—the 1:2:4 etc. rule being too limited for supplying the varying requirements found in actual practice. Honeycombed pours are not rare and subsequent plastering-over neither protects the metal reinforcements from the weathering agencies nor does more than deceive the observer as to its quality. The addition of mineral soaps and oils on a large scale would be a serious item of cost in rendering all concrete waterproof. Certain mineral colloids seem to offer an excellent means of cutting down the volume of pore space. However, while chemists and engineers seek a means of checking the corrosion, why not change the design of reinforcements so that this internal pressure will not have to be counteracted by the low tensile strength of concrete? A trial might be made on heavy rolled metal fabricated with a pipe machine but not welded at the lap. Lateral strains produced by the increment in volume of the reinforcements due to rust would be absorbed by deflecting the tubular bars.

## Germany's Finger

### In the Platinum Pie

**E**DITORIAL comment under this caption in our issue for August 15 has been the subject of some criticism, particularly as relating to Mr. Charles Engelhard and his business associates. Needless to say, our opinion then expressed was based on what we believed to be authentic and reliable information. As to that part of our remarks suggesting the possible influence of Mr. Engelhard in fixing the price paid by our Government for some 20,000 ounces of platinum brought from Russia, he himself has already entered a denial which we have published and accepted at its face value.

Since that time we have had an opportunity to gain

additional information from sworn statements of Mr. Engelhard, in which he disclosed the details of his relations with the German house of Heraeus and the former interest of Heraeus in the American Platinum Works and Baker & Co. These affidavits show that the German interest in these American platinum corporations, as represented by Heraeus, amounted at one time to 20 per cent, but that about April 1916, or nearly one year prior to our declaration of war with Germany, Mr. Engelhard acquired the entire Heraeus interest in the two companies. Since that time it appears that there has been no enemy or ally-of-enemy interest in either of them. We are further advised that Mr. Engelhard has caused a minute to be entered on the records of the several companies in which he is interested, to the effect that he will not reconvey any stock to Dr. Heraeus at the close of the war, without the unanimous approval of all the stockholders of record.

It appears that Mr. Engelhard has been fully investigated on these points, as well as on his entire business career in this country, by several branches of the Government. Unfortunately the Government does not officially announce the results of such investigations nor publicly state its opinion regarding the loyalty of the individuals investigated. As one official explained it to us, the evidence is presumptively in the individual's favor if no action is taken against him. Thus, while we have been unable to secure from any official or agent of the Government any statement as to the result of the investigations, we presume it was favorable to Mr. Engelhard and satisfactory to the Government. Since there was no malice in our original remarks nor any desire to do an injustice to Mr. Engelhard, we are glad to correct any false impression we may have created as to his loyalty or the German control of his companies.

### Coke, Pig Iron and Transportation

PRODUCTION of pig iron in the first half of 1918 is officially reported at 18,227,730 gross tons, which is more than a million tons less than the production in any one of the four preceding half years, and 1,600,000 tons less than the production in the latter half of 1916. The blast-furnace capacity had meanwhile undergone a very considerable increase. The failure in production in the first half of this year was due to shortage of coke and the shortage of coke was due to the railroad breakdown whereby by-product coke production was curtailed materially and beehive coke production curtailed a great deal. All the loss in pig iron production occurred during the first quarter of the year. Production in the second quarter was more than 10,000,000 tons, or at a rate greater than obtained in any preceding half year. Production in the third quarter was substantially the same, and production in the current quarter promises to be much heavier.

The Railroad Administration insists that there is not the least likelihood of a railroad breakdown this winter at all comparable to that of last winter and no doubt the balance of probabilities lies strongly in that direction. The railroads are much better organized, the shipments are much better controlled so that they do not tend to produce congestion as they did a year ago,

and a repetition of last winter's altogether exceptional weather is of course unlikely.

Even though pig iron production conditions have been much less unsatisfactory in recent months than in the first three months of the year they have not been really satisfactory by any means, as the output has not been as much as would be expected from the capacity of the furnaces in blast. A thorough investigation of the matter was undertaken nearly two months ago and the blast furnaces laid most of the blame on the character of the coke they were receiving, there being much coke of poor structure and much coke with too much ash, the former indicating carelessness in burning, the latter carelessness in mining. The Fuel Administration accordingly inaugurated a strenuous campaign to bring about the production of coke of better quality, and some results have lately begun to be apparent.

The importance of coke quality cannot be overestimated. The production of coke has been approximately equal to the requirements of the blast furnaces for months past, the cases of coke shortage being few and far between. Better coke means more pig iron per furnace, and as a total. More pig iron means more steel, for the steel works are not fully supplied with pig iron in relation to their capacity, and every ton of steel helps to win the war. The control of steel by the War Industries Board, rigid for several months and constantly growing more rigid, insures that every additional ton of steel made will be placed where it will do good.

The production of by-product coke has increased even more rapidly than was expected. In this department two months ago there was a survey of the situation as to the completion of by-product ovens, and it was estimated, conservatively, that by the end of the year there would be 615,000 net tons per week rated capacity in by-product coke, which with a 90 per cent efficiency, about what had been shown in the past, would mean an output of 550,000 tons a week. Two months later, however, we have the Geological Survey report for the week ended September 28, showing a rated capacity of 624,910 tons, a production of 576,254 tons, and a proportion of production to rated capacity of 92.2 per cent. This high percentage was probably fortuitous, for every one of the separate causes of loss was exceptionally low—coal shortage, labor trouble, repairs and miscellaneous. In the same week the production of beehive coke was 612,000 tons, making a total of 1,188,000 tons of coke produced in the week, representing a rate of 62,000,000 tons a year.

The normal function of a by-product coking plant is to make coke as a product and certain other things as by-products. That is not precisely the alignment in war time. The Clairton plant in the Pittsburgh district, where seven batteries of 64 ovens each are now in operation, with three more batteries to follow very shortly, is operating on high volatile coal from the Klondike region, when physical conditions would permit the use of the lower volatile coal of the Old Basin, because the output of toluol and sulphate of ammonia is correspondingly increased. On 19 hours' coking time the plant is showing 1,000 tons coal consumption and 650 tons coke production per battery per day. The Old Basin coals run 70 per cent and upwards while the Klondike coals are all well below 70 per cent.

### Effect of Oxygen on Precipitation of Cyanide Solutions

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—In the September 15th issue of *CHEMICAL & METALLURGICAL ENGINEERING*, in the discussion of Mr. Thomas B. Crowe's paper on "The Effect of Oxygen Upon the Precipitation of Metals from Cyanide Solutions," I note that you attribute the following remarks to me:

"Chairman Clevenger said that without endeavoring to detract from Mr. Crowe's work in the least he thought that the same thing had been done inadvertently in vacuum filtering, in the Butter's type machine, for many years."

This statement as it appears could readily be construed as meaning that although unconscious of what they were doing all operators of vacuum filters had removed the air from their cyanide solutions prior to precipitation. Furthermore, it might be assumed that Mr. Crowe's development lacked patentable novelty.

My introductory remarks as taken from the stenographic report of the meeting were as follows:

"I am sure that Mr. Crowe's paper will prove of a great deal of interest to cyanide operators as it is a distinct new development in cyanidation. After reading the paper, it occurred to me that some of us had done practically the same thing sometime ago, but that we had done so without design and unconsciously. I refer particularly to the operation of some of the earlier types of vacuum filter with which was used a dry-vacuum pump and a receiver. This is similar equipment to that employed by Mr. Crowe, and it is obvious that all solution passing through the filter under this condition would have its air removed.

"However, we did not know the good effects that we were getting from such of this solution as was precipitated, and it has remained for Mr. Crowe to bring sharply to our attention the advantages of removing air from cyanide solutions prior to precipitation. I feel sure that we will all give him full credit for this clever improvement in the cyanide process."

During the discussion the further observation was made:

"It is the case of one of those obviously simple things when you see it in operation, yet something that we have all overlooked despite the fact that we have operated vacuum filters."

It will be noted that I referred particularly to the operation of some of the earlier types of vacuum filters with which was used a dry-vacuum pump and receiver. As a matter of fact the dry-vacuum pump and receiver were discontinued for later installations in favor of the wet-vacuum pump, on account of the greater simplicity of the arrangement, there being required no receiver, and so-called barometric leg for continuously discharging the solution from the receiver without breaking the vacuum.

It is obvious that in installations employing the wet-vacuum pump little or no air would be removed from the solution. In installations employing the dry-vacuum pump the air was removed only from such solution as passed the filter. In the operation of filters of all types it has been long recognized that thick pulp can be most efficiently filtered; or, in other words, the smaller the proportion of the solution which it is necessary to force through the filtering medium in forming the

cake, the greater the capacity of a given unit. The whole of the pregnant solution precipitated was, therefore, never passed through the filter. Practice regarding the proportion of solution from the filter which was precipitated varied. In many cases the amount of such solution precipitated was small, and in some cases none of it was precipitated.

On the whole it is, therefore, clear that in vacuum filtration as practiced in recent years, no benefit has been derived through the removal of air from solutions passing the filter.

Mr. Crowe has been the first to point out that it was advantageous to remove dissolved air from pregnant solutions prior to precipitation, and acting upon this knowledge he has been the first to apply a vacuum to all the pregnant solution prior to precipitation. Therefore, there can be no question regarding the originality of his invention.

G. H. CLEVINGER.

Colorado Springs, Colo.

### Germany's Finger in the Platinum Pie

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Our attention has been called to the editorial in your issue of August 15, entitled "Germany's Finger in the Platinum Pie" and we wish to protest against the statements made therein so far as concerns our firm.

As you may know, we have acted as agents for the British Government in regard to platinum during the war.

Your statement that "Heraeus also is said to have owned a one-fifth interest in Johnson Matthey & Co.," is wholly incorrect. Neither Heraeus, nor any German individual, partnership or corporation owns or at any time has owned any interest whatsoever in Johnson Matthey & Co. Our stock is and has always been held exclusively by British proprietors.

JOHNSON MATTHEY & CO., LTD.

London, England.

### Chemical Questionnaire Not a Call to Service

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—General Sibert directs me to extend to you the thanks of the Chemical Warfare Service of the United States Army for your assistance in the census of American chemists recently made by this arm of the service. Without the aid of your journal it would have been impossible to have gained such wide publicity for the enterprise, or to have obtained such a prompt and altogether satisfactory response from the great body of loyal chemists of this country. Well over half the questionnaires have been answered within the first three weeks of the campaign, and the rest are daily being received in such numbers as to indicate the completion of the task at a not far distant date. The War Department is thus put in possession of an invaluable set of records at extremely small expense.

While the purpose of the questionnaire has been understood by nearly all of those who have replied to it, there have been a few instances in which it has been mistaken-

ly interpreted as a call to immediate service. In order to avoid any misunderstanding it should be explained that the purpose of the census is primarily to put the War Department in control of complete information as to the chemical man-power of the country, not to gain immediate recruits for the Chemical Warfare Service. At the present time the vacancies in the Service are comparatively few in number. When vacancies occur in the future, reference will be had to the tabulated information gleaned from the present census, and appointments will be made from the names on file, attention being paid to the applicant's technical qualifications, desire to serve, etc.

The great majority of American chemists will undoubtedly never be called upon to serve in a military capacity in the present war. The Government, however, must have complete information concerning all chemists, in order that it may select those best fitted to perform its work, and at the same time interfere as little as possible with established essential industries. The chemist who, after returning his completed questionnaire, receives no call to service may take it for granted that the Government cannot, for the time being, utilize his services. In the meantime three things are asked of him:

1. To keep the Chemical Warfare Service informed of any change in his address, his employment, his draft status or anything else which might have a bearing on his case.

2. To notify the Chemical Warfare Service at once if he is drafted and called to camp. In such a case he should give his complete military address.

3. To help stabilize the industry of the country by continuing steadily at essential work until the Government notifies him that his services are needed elsewhere.

In addition it is requested that all persons send to the Chemical Warfare Service the names and addresses of any chemists of their acquaintance who have not already received the questionnaire. Chemists who have already received the questionnaire but who have not yet returned it should do so at once, in order that the Government may not be put to the trouble of sending out a large number of follow-up letters. Any chemist who has not received the questionnaire should write for a copy, addressing his request to the Personnel Section, Administration Division, Chemical Warfare Service, U. S. A., 7th and B Streets, N.W., Washington, D. C.

F. E. BREITHUT,

Major Chemical Warfare Service,  
Chief of Personnel.

Washington, D. C.

## Refractory Tube Made in the Laboratory

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—A research chemist of the writer's acquaintance recently found it necessary to use a refractory tube of dimensions not carried in stock by any of the dealers of his locality. Being put to the necessity of making what he wanted he proceeded as follows:

Calined fire-clay ground to pass a fifty-mesh screen was mixed to a paste of such consistency that it could be poured with difficulty. An iron pipe of the desired dimensions was filled with this clay and after shaking until the clay was thoroughly stuck to the pipe the excess was poured out. The pipe was then placed in a

horizontal position and turned slowly until the clay was set. This required but a few minutes. When the clay was set the pipe was attached to an aspirator and a gentle current of air was drawn through the pipe until it was dry; it was then placed in the furnace and burned at the proper temperature, when it was ready for use. This pipe gave perfect satisfaction and was good for any temperature to the melting point of iron. The lining was used to protect the iron from the materials used in the experiment.

JOHN C. BAILAR.

Golden, Colo.

## Removing Plugs from Steel Drums

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—Frequently the threaded plugs in steel drums, especially those containing corrosive chemicals, offer such resistance when an attempt is made to remove them that a cold chisel and hammer have to be resorted to. This usually renders the drum worthless for further use, and if the contents are not used immediately, they must be transferred to another container.

This trouble can be obviated by a simple method which can be applied with the ordinary tools around a plant. When the usual methods fail to remove the plug, if a slot is sawed through the center of it with an ordinary hack saw and several sharp blows struck at right angles to the slot with a hammer, and a large pipe wrench applied, the plug will come out easily. The slot allows the plug to yield sufficiently to loosen the threads and does not spoil the plug for use.

M. EDWARD BOYD.

Washington, D. C.

## Honorary Doctorates at the Chemists' Club

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—William, he of the dusky countenance and ample girth who erstwhile greeted the members of the Chemists' Club as they entered its portals, has passed away. For a year or more there had been trouble, sometimes with his health, sometimes with his disposition, and as a sequence of the latter irregularity there followed occasional measures of reproof from the house committee. But these are all at an end now and it is our pious hope that clad in golden slippers his airy steps are guided along the jasper streets by Old Black Joe, Uncle Ned, the lovely Nellie Gray and Aunt Dirah of the Quilting Party from the Old Kentucky Home. Perhaps he may even find an abundance of those Kentucky spirits which in life he loved too well and which we shall soon seek in vain.

His memory will always be distinguished because it was he who founded, originated and impersonated the only institution that conferred an honorary doctorate upon every member of the Club. Some of these were merely confirmatory of academic honors already achieved either at home or abroad, and as such they call for no comment. Others again were wholly original and preceded the titles which are anticipated every June, *honoris causa*, by a vast number of the chemists of America. William was the pioneer in these endowments of the mind. To him, every person elected became a Doctor as soon as he qualified in his membership. These titles were known as William's College Degrees.

## Western Chemical and Metallurgical Field

### Smelting in British Columbia

The dormant investigation of British Columbian smelter schedules authorized by the Dominion Government but halted by lack of funds, will probably be revived by lead-ore shippers following the increase of 45 cents per ton under Schedule B announced recently by the Trail Smelter. S. G. Blaylock, the assistant general manager of the smelting company, in a letter to producers, cites the following increases in smelting expense causing the increase:

Cost of coke increased 40 cents per ton at ovens, equalling an increase of 10 cents per ton on ore.

Wages increased 30 cents per shift, equalling an increase of 45 cents per ton on ore.

Increases in freights on both coke and bullion also went into effect at about the same time, so that in addition to the above increase, all settlements will be reduced by the actual increase in transportation cost.

The Grand Forks smelter of the Granby Consolidated Co., has been shut down. Its closure has been foreshadowed for a year or more by the rapidly increasing costs of mining and smelting and the decreasing tenure of ore received from the Phoenix mines, its main source of supply. Operations at Grand Forks have therefore gradually been curtailed. The recent increase in the price of copper was absorbed immediately by increased freight and labor costs. Consequently the main operations of the Granby Company have shifted to the coast, where the Anyox smelter, handling ore from the Hidden Creek mine, is producing a large amount of copper at a much lower cost.

The Ladysmith smelter has recently indulged in another short campaign, but rapidly exhausted the accumulation of ore on hand. Operations of this sort are today somewhat of an anachronism, reminiscent of the times when blast-furnace operations were controlled by the fracture of slag and matte buttons.

Meanwhile, the Provincial Government has taken an active interest in the exploitation of their large resources in iron ore. Alfred Stansfield has spent the summer investigating the possibility of smelting these ores in the electric furnace, and his report is awaited with much interest by the entire Pacific Coast. Without anticipating his findings, it may be stated that electric pig iron probably could be financed by Californians if gray iron could be produced, lower in silicon and higher in graphitic carbon than the usual electric pig. The latter is not acceptable to the foundrymen in that region, although it is excellent material for steel furnace. Electric steel in competition with open-hearth products merchant and structural shapes would require energy at a cost per kilowatt-hour but a fraction of any present quotation in that region.

**Porphyry Coppers Summary.**—A tabular representation of the performance of the various mills at Utah Copper, Chino, Ray and Nevada Consolidated for the year 1917 is given herewith, together with a comparison of the results for the preceding year. The costs in every case show large increases. Except in the case of Nevada Consolidated they seem to be figured on the same basis and allow for smelter deductions, are

credited with precious metal values and miscellaneous income, are charged with all overhead charges, transportation, refining and selling costs, 5 per cent for depreciation, and a large reserve estimated to cover Federal and other taxes to become due in the immediate future.

The low recovery of the mills of the Utah Copper Co. is said to be due to the use of a lower grade ore than usual, interference by reconstruction in the plants themselves, and to the crowding through of a maximum tonnage (they are running 60 per cent over their normal economic capacity). The revision of the fine-crushing department at the Magna Plant continues slowly. Much work was done at the Arthur Plant. The fine-grinding department was reconstructed and new facilities installed for handling concentrates and tailings. The construction of a new tailings dam covering a largely increased area below the mills and necessitating the revision of several miles of main line railway track was rapidly pushed. The leaching plant was completed, and was being started up at the end of the year. A new coarse-crushing department was designed in order to eliminate delays in handling frozen cars in winter, consisting of a car tippie and a very large crusher, together with the necessary auxiliaries.

At Hurley, New Mexico, additions to the concentration machinery in the original five sections of the Chino mill were completed about the middle of the year, and with the second unit of the crushing plant in operation at Santa Rita an additional tonnage of 11 per cent was immediately treated. The construction of Section 6 was nearly completed, and a flow sheet for Section 7 (to handle 500 tons of oxidized ores in addition to a large amount of sulphides) was worked out from the operation of the 100-ton experimental plant. The good results to be expected from the oxide mill caused the abandonment of further construction of the tailings retreatment plant.

At the Ray concentrator at Hayden, Arizona, an increased copper recovery of 18 per cent was effected on but a 7 per cent increase in ore treated. This result was effected by methods worked out largely by the local

STATISTICS OF JACKLING PROPERTIES

staff, increasing the efficiency of all departments of the plant. During the year a new system of slimes treatment was developed and installed to give final recoveries on 75 per cent of the total tonnage. The recovery of sulphide copper in Ray ores amounts to 83.32 per cent, but only 33.48 per cent of the contents in oxide- and carbonate-copper is saved.

Three-quarters of a million dollars in new construction was expended at the plants of the Nevada Consolidated, mainly for a new crushing plant at the mill, and a plant for pulverizing coal to replace oil as a fuel in the reverberatory furnaces. The coarse-crushing division of the mill now delivers the entire mill tonnage at about 1-inch size, this relieving the fine-crushing departments of their overload. Tube mills have also been installed in the regrinding sections. The recovery of copper from company ores shows a sharp decrease; but as a matter of fact the copper produced in concentrates by the mill was about the same as before, the balance being made up from ores treated on a custom basis.

#### Ore-Dressing Activities of the Bureau of Mines

THE Salt Lake station of the Bureau of Mines is about to occupy a substantial office and laboratory building, erected at a cost of about \$35,000, at a spot alongside the present ore-dressing laboratory. The new building was made possible largely by the coöperation of several mining companies in Utah, who donated perhaps half of the funds for its erection. Besides offices for the superintendent, metallurgist, chemist, and their clerical help, it will contain the laboratories for chemical and microscopic analysis, together with a large library. The University of Utah benefits from the erection of the building by having office quarters for the head of the metallurgical department, as well as a large lecture room at the north end of the building. Thomas Varley has been transferred from the Seattle station to become acting superintendent of the Salt Lake station, where it is possible that the ore-dressing work of the Bureau will become centralized. The present milling equipment, which is unusually complete, suffers in that it requires a considerable tonnage of ore upon which to operate. Consequently the apparatus is being rearranged and remodeled so that lots of a few hundred pounds can be efficiently studied. Mr. Varley has been succeeded in Seattle by Mr. F. F. OVITZ, Fuel Engineer. Work at that point will consist largely of fuel investigations under the direction of the superintendent, and electro-metallurgical work directed by Mr. F. C. RYAN.

#### New Explosives Plant for California

The erection of a TNT plant at Giant, Cal., has been authorized. The estimated cost is \$1,438,000. This plant is to be located on land adjacent to the nitric acid plant of the Giant Powder Company, located at Giant, Cal. The land belongs to the powder company and is to be leased to the Government with option on the part of the Government to renew in yearly periods. The government is to remove the plant whenever it feels that the plant's further maintenance is unnecessary. The contractor will be Grant Smith and Company, of Seattle, Washington. The construction work is to be under the supervision of the Construction Division of the Army. The finished plant will be operated by the Giant Powder Company.

Ninety-day contracts can now be made by manufacturers of sulphuric, nitric and muriatic acids through 1919, giving the government preferential rights if needed for its war requirements at the schedule prices.

## Stringent Regulations on Platinum

WHILE no reliable data has ever been available on platinum production, because much of the Russian output has intentionally not been reported in order to avoid taxes, Prof. J. L. Howe has recently estimated the limits of production in the world up to January 1917 in troy ounces as:

|                     | Minimum   | Maximum    |
|---------------------|-----------|------------|
| Russia .....        | 7,115,482 | 10,128,308 |
| Colombia .....      | 700,000   | 735,000    |
| Borneo .....        | 175,000   | 200,000    |
| United States ..... | 10,000    | 12,000     |
| Canada .....        | 9,000     | 10,000     |
| Miscellaneous ..... | 9,000     | 12,000     |
|                     | 8,018,482 | 11,095,308 |

About 10 per cent of the above is undoubtedly in the United States, but how it is distributed and utilized is not known. Since the catalytic process plants for manufacturing sulphuric and nitric acids are being installed on such a large scale, it is estimated that about 12 per cent of our million ounces of platinum will be used in the 3,000,000-ton catalytic vitriol output. One ounce of platinum is needed for the production of twenty-five tons of catalytic sulphuric acid or forty tons of nitric acid from ammonium per annum.

Now that the Russian supplies are shut off, it has become important that our scattered domestic stocks be inventoried, so that if the need should arise, requisitions can be taken efficiently and with the least hazard to scientific development. Mr. C. H. Conner, chief of the platinum section of the War Industries Board, wishes it known that it is desired to disturb the trade as little as possible but that the co-operation of all citizens in the enforcement of the platinum regulations is essential:

#### REGULATIONS.

The following regulations are hereby promulgated under the provisions of the act of October 6, 1917 (40 Stat., 385), as amended by the act of July 1, 1918 (Public, No. 181), authorizing the Director of the Bureau of Mines, under rules and regulations approved by the Secretary of the Interior, to limit, during the period of the war, the sale, possession, and use of platinum, iridium, and palladium, and compounds thereof:

SECTION I. The War Industries Board is hereby designated under section 21 of the act of October 6, 1917, and the President's proclamation of October 26, 1917, as the agent of the Director of the Bureau of Mines in the execution of the regulations as hereinafter indicated.

SEC. 11. From and after the date of these regulations, under the penalties prescribed by section 19 of the act of October 6, 1917, no person<sup>1</sup> shall:

PAR. a. Use any platinum or platinum scrap, iridium, or iridium scrap, palladium or palladium scrap, and/or compounds thereof, in the manufacture, alteration, or repair of any ornament or article of jewelry.

PAR. b. Manufacture for use in dentistry any metal, metal parts, or alloys containing more than 20 per cent by weight of platinum or 40 per cent by weight of platinum, iridium, and/or palladium combined, or manufacture supplies therefrom.

SEC. 111. From and after the date of these regulations, under the penalties prescribed by section 19 of the act of October 6, 1917, no person shall without a license—

<sup>1</sup>Section 19 of the act of Oct. 6, 1917, is as follows: "That any person violating any of the provisions of this act, or any rules or regulations made thereunder, shall be guilty of misdemeanor, and shall be punished by a fine of not more than \$5,000, or by imprisonment not more than one year, or by both such fine and imprisonment."

<sup>2</sup>The word "person," for the purposes of these regulations, shall be construed in accordance with the definition contained in section 4 of the act of Oct. 6, 1917, which is as follows:

"That the word 'person' when used herein shall include States, Territories, the District of Columbia, Alaska, and other dependencies of the United States, and municipal subdivisions thereof, individual citizens, firms, associations, societies, and corporations of the United States and of other countries at peace with the United States."

PAR. a. Purchase, sell, barter, or deal in unmanufactured platinum, iridium, or palladium, or compounds thereof (including crude, scrap, filings, polishings, or sweeps), except that sales may be made without a license to an authorized agent of the United States or to a licensee authorized to purchase the same; or possess for more than 90 days after the date of these regulations one ounce troy, or more, of such unmanufactured platinum, iridium, palladium, or compounds thereof.

PAR. b. Possess, use, sell, purchase, or barter, for purposes connected with his business, platinum, iridium, palladium, or compounds thereof (except that sales may be made without license to an authorized agent of the United States, or to licensee authorized to purchase the same), if such person be engaged in—

No. 1. Producing platinum, iridium, or palladium, or compounds thereof, by mining.

No. 2. Producing sulphuric acid, nitric acid, or other chemical products where platinum, iridium, palladium, or compounds thereof are used in such production.

No. 3. Importing or exporting platinum, iridium, or palladium, or compounds thereof.

No. 4. Producing platinum, iridium, or palladium, or compounds thereof, either as a primary product or as a by-product of smelting or refining.

No. 5. Manufacturing electrical appliances and/or parts thereof containing platinum, iridium, or palladium, or compounds thereof.

No. 6. Manufacturing surgical appliances and X-ray apparatus containing platinum, iridium, or palladium, or compounds thereof.

No. 7. Manufacturing chemical apparatus and reagents of all kinds containing platinum, iridium, or palladium, or compounds thereof.

No. 8. Conducting or operating chemical laboratories in which platinum, iridium, or palladium, or compounds thereof, are used.

No. 9. Manufacturing scientific instruments containing platinum, iridium, or palladium, or compounds thereof.

No. 10. Manufacturing and/or distributing dental supplies containing platinum, iridium, or palladium, or compounds thereof.

No. 11. Manufacturing and/or dealing in jewelry containing platinum, iridium, or palladium or compounds thereof.

No. 12. Manufacturing or producing any article or product not mentioned above where such business requires more than one ounce troy per month of platinum, iridium, or palladium or compounds thereof.

SEC. IV. Applications for licenses shall be made under oath to any licensing agent duly authorized under the act of October 6, 1917, as provided in the regulations issued under this act.

SEC. V. Every applicant for license will be required to submit with his application a sworn inventory of all platinum, iridium or palladium or compounds thereof in his possession or control; and every licensee will be required to submit at such times as may be designated by the War Industries Board a sworn inventory of his holdings of platinum, iridium, or palladium or compounds thereof in whatever form they may be.

The Director of the Bureau of Mines, at the request of the War Industries Board, may at any time require from any user or possessor a detailed sworn inventory of any and all materials held by him containing platinum, iridium, palladium or compounds thereof, and such inventory must be furnished promptly upon receipt of such requirement.

SEC. VI. All licenses shall be issued in the name of the Director of the Bureau of Mines and countersigned and delivered by the War Industries Board, and shall be, and remain subject to the following conditions:

PAR. a. Each license shall contain such appropriate conditions as the Bureau of Mines, through the War Industries Board, may impose.

PAR. b. The Bureau of Mines through the War Industries Board may change the conditions of the license from time to time, as it may deem necessary.

PAR. c. Records shall be kept by each licensee of all his sales, purchases and other transfers of platinum, iridium or palladium or compounds thereof, and of articles containing platinum, iridium, or palladium or compounds thereof, with the names and addresses of the purchasers, sellers, and/or transferees, and the quantities involved, which records shall be open at all times to the duly authorized representative of the Director of the Bureau of Mines.

PAR. d. Any and all platinum, iridium, or palladium, or compounds thereof, acquired under the authority of such license shall be used strictly for the purposes and in the manner stated in such license.

PAR. e. Upon request of the War Industries Board, the licensee shall report the prices at which sales of his products containing platinum, iridium, or palladium, or compounds thereof, are being made; and the right to prohibit further sale of such articles at prices deemed exorbitant by it is reserved to the War Industries Board.

SEC. VII. Any licenses issued hereunder may be revoked for violation of any of these regulations, or for violation of any of the conditions contained in such license, or if such revocation is deemed necessary or advisable for purposes of the national security and common defense.

SEC. VIII. The War Industries Board will, upon request, furnish a list of Government agents or licensees authorized to purchase platinum, iridium, or palladium, or compounds thereof. Neither the United States nor its representatives will assume any responsibility, financial or otherwise, where sales are made to licensees.

SEC. IX. The prices at which platinum, iridium, or palladium will be purchased by a duly authorized agent of the United States or by such licensee as may be authorized to purchase or sell platinum, iridium, or palladium, or compounds thereof, will be such prices as may be determined by the proper governmental agency authorized to determine such prices.

SEC. X. Whenever such Government agents and such licensees as may be authorized to purchase platinum, iridium, or palladium or compounds thereof, shall refuse to purchase the same from any person who is compelled by these regulations to sell the same, or is forbidden by these regulations to possess or use the same, then such person shall promptly notify the Platinum Section, War Industries Board, Washington, D. C.

SEC. XI. These regulations shall not operate to relieve any person upon whom an order requisitioning platinum, iridium, or palladium or compounds thereof may have been or may hereafter be served, from any obligation imposed upon him by such order.

SEC. XII. These regulations are supplemental and amendatory to the regulations heretofore issued under the Explosives Act of October 6, 1917.

VAN. H. MANNING,  
Director of Bureau of Mines.

Approved, August 17, 1918.

FRANKLIN K. LANE,  
Secretary of the Interior.

## Use of Perchloric Acid as a Substitute for Platinum in Potash Analysis

Precipitate the sulphates present with barium chloride (slight excess) in strong HCl solution, boil and filter off the barium sulphate, if present. Evaporate to dryness and heat until all ammonium salts are driven off—below, red heat so as not to volatilize any KCl. Dissolve in 20 cc. hot water and add a quantity of HClO<sub>4</sub> sufficient to combine with all bases present. Evaporate without stirring, cool, and dissolve residue in hot water. Add HClO<sub>4</sub>, and again evaporate until the heavy white fumes of perchloric acid are given off. Be sure to cool. Take up with 25 cc. 96-97% alcohol containing 0.2% by weight of HClO<sub>4</sub> (1 cc. 60% acid per 300 cc. 97-98% alcohol), breaking up residue with stirring rod. Decant through a weighed Gooch crucible containing a mat which has been washed with the above wash alcohol. Wash once again with the wash alcohol, decant, and transfer the filtrate to the crucible. Wash several times with wash alcohol, dry for an hour at 120-130° C., cool and weigh. The residue is KClO<sub>4</sub>. Dissolve this off with hot water and the crucible is ready for another determination. The accuracy should average between one-half and one-tenth of one per cent.

# Fall Meeting of the American Electrochemical Society

The Principal Feature of the Meeting Was a Symposium on Electrochemical Industries After the War, in Which Specialists Discussed Various Post-War Problems—Meetings for 1919 Will Be Held in New York City and Chicago

THE annual fall meeting of the American Electrochemical Society had originally been planned for Princeton, Sept. 30 to Oct. 2, but owing to the commandeering of the University of Princeton by the Government, the meeting place was changed to Atlantic City. An unusually attractive technical program and the very favorable weather brought the unexpected total attendance to 115. The seriousness of the times was reflected in the program; there were no social functions whatsoever and the main feature was the all-day symposium on "Electrochemistry After the War." The

The occluded element, hydrogen or oxygen, is less closely combined with the solvent metal than is the solute in a solid solution. The form of hydrogen that causes the platinum wire to expand is very likely different from the form that produces the commonly observed increase of resistance during occlusion, but is possibly identical with the hydrogen that causes a diminution of the resistivity of the metal.

In the discussion of Professor Smith's paper, Dr. J. W. RICHARDS referred to the decrease in resistivity of alloys treated in hydrogen, in particular ferrocerium.

AMERICAN ELECTROCHEMICAL SOCIETY AT ATLANTIC CITY, SEPTEMBER 30, 1918

meeting was opened by President F. J. Tone in the Belvedere room of the Hotel Traymore.

The first paper on the program was presented by Professor DONALD P. SMITH of Princeton University on

## PROCESSES WITHIN THE ELECTRODE WHICH ACCOMPANY THE DISCHARGE OF HYDROGEN AND OXYGEN

The effect of the occlusion of hydrogen and oxygen by various metals was investigated. Small wires of palladium, platinum, tantalum and iron were used as anodes and cathodes and changes in electrical resistance and length of wire due to the occlusion of gases were determined. It is well known that when palladium occludes hydrogen, either electrolytically or from exposure to the gas, a marked increase in the electrical resistance of the metal results. Smith found, however, that when a fine platinum wire was made cathode at a current density of about 0.3 amperes per square decimeter, the ohmic resistance of the platinum wire decreased during occlusion of hydrogen until it reached a steady value. Similar results were obtained with oxygen in the case of palladium wires. In general it may be said that both hydrogen and oxygen first enter an electrode in a transitional condition in which they possess a conductance of their own. It appears that this conducting form of hydrogen is not intimately united to the solvent metal, but exists in a state which resembles rather one of mere mechanical enclosure, and this view is supported by the fact that the wires stretch during occlusion. Upon removal of the occluded gas the wires assume their original length and resistivity.

Mr. W. R. MOTT of the National Carbon Company, pointed out that it had always been difficult to place hydrogen in the periodic system and that perhaps the monatomic modification would fit in well in the metal group. In answer to a query by Major FRARY, Professor Smith pointed out that the elongation of the platinum and palladium wires during occlusion does not exceed the elastic limit.

## THE SIGN OF THE POTENTIAL

Professor O. P. WATTS of Wisconsin University next presented a paper on the Sign of the Potential. This question has been the source of long discussions at previous meetings of the Society and the present paper is what might be called the "minority report." Professor Watts argues in favor of the plus sign for the potential of zinc. His strongest argument is that according to present conceptions, the electric current is a flow of negative electrons and these electrons can flow only to material of relatively higher or more positive potential. Messrs. FRARY, FITZGERALD, MOTT, FINK and RICHARDS discussed the paper. The majority favored the adoption of the minus sign by the Society and to have all papers published in the Transactions adhere to the adopted standard.

## SEPARATION OF RADIUM EMANATION AND ITS DETERMINATION ELECTROSCOPICALLY

Mr. J. E. UNDERWOOD of the Bureau of Mines, Golden, Colorado and Professor HERMAN SCHLUNDT of the University of Missouri described an apparatus and method for determining radium in various ores and concen-

trates. The apparatus has proved very serviceable for determining the radium content of monazite sand and the concentrates obtained therefrom in the extraction of mesothorium from this ore.

#### THE EFFECT OF RADIUM EMANATION ON THE HYDROGEN-OXYGEN EQUILIBRIUM

Dr. S. C. LIND, radio chemist of the Bureau of Mines, reported upon an experimental investigation on the Heterogeneous Equilibrium of Hydrogen and Oxygen Mixed with Radium Emanation. Dr. Lind found "that an electrolytic mixture of hydrogen and oxygen gases, when mixed with radium emanation in a spherical bulb of 2 cm. diameter, will combine at ordinary temperature to an extent of nearly 99 per cent of completion, before equilibrium is reached. Through comparison of the known relative efficiencies of alpha rays in bringing about (1) the combination of hydrogen and oxygen, and (2) the decomposition of water, equilibrium would be expected at about 50 per cent of complete combination, if the  $H_2O$  vapor were condensed evenly over the whole inner surface of the reaction bulb. Localized condensation of water will not affect its rate of decomposition until the depth of the layer exceeds the range of the alpha ray in water. This takes place when its area is about 1/35 of the total area. Further localization results in diminishing the opportunity for the decomposition of water and a consequent shifting of the equilibrium toward recombination. The limit would be reached with all the water condensed in a single semi-spherical drop. The equilibrium is then calculated to be 95.5 per cent of total combination. When the quantity of water in the system is large, very high gaseous pressures would be produced before equilibrium results. A theory is advanced that the high pressure produced when an imperfectly dried radium chloride, or bromide, is sealed in a small tube, is due to hydrogen alone, not to a mixture of hydrogen and oxygen, the oxygen having been bound chemically as a basic salt."

#### MILITARY APPLICATIONS OF ELECTROPLATING

Dr. WILLIAM BLUM of the Bureau of Standards gave a very interesting outline of the Bureau's suggested Classification of Protective Coatings on Metal Parts of Military Supplies. For steel or brass which requires protection only during storage and transportation a protective coating of grease, slushing oil or similar compound is to be used; for steel or brass for indoor use or for mild exposure, any protective coating that will produce the desired color appearance and resistance to abrasion. This coating may be applied electrolytically, as for example nickel-plate, or chemically as by the copper nitrate process; or mechanically, as, for example, enamel. For steel subject to moderate outdoor exposure, zinc plating should be given preference. For steel exposed to severe outdoor conditions zinc coatings only should be employed. For steel requiring special protection against corrosive liquids, for example, gas shells, lead plating is to be used. For metal to be used in contact with food, nickel or silver plating, tinning or silicate enamels are prescribed.

#### IRON THAT CAN BE WHITTLED WITH A JACK KNIFE

Mr. F. C. KELLEY of the General Electric Company annealed samples of American ingot iron in an atmos-

phere of hydrogen for three hours at 900 to 950 deg. C. Upon testing the hardness of same he found that it was only 20 points higher than dead-soft copper on the Brinell scale. If annealed copper and annealed iron are each worked to produce a one-third reduction in thickness, the hardness of the copper increases over 100 per cent, while iron increases only about 60 per cent. In the discussion of Mr. Kelley's experiments, COLIN G. FINK pointed out that the hydrogen anneal of the ferronickel core of his leading-in wire was an important step in the process of manufacture of the wire, since the hardness of the core and copper shell must be about the same to insure a constant proportion of copper to core to the very last die in the drawing process.

#### NITRIC ACID BY THE ELECTRIC ARC PROCESSES

Mr. E. KILBURN SCOTT of Manchester, England, gave an interesting exposition of the various arc processes for the fixation of atmospheric nitrogen. He described at length the operation of his own furnace and pointed out the various advantages over other types. The paper was discussed by Messrs. ATWATER and LANDIS. The conical arc flame of the Kilburn Scott furnace is its most characteristic feature. The paper will be reviewed in extended form in a later issue.

#### HIGH-TEMPERATURE RESEARCH

Mr. W. R. MOTT of the National Carbon Company reported upon experiments he had carried out in the carbon arc to determine the Relative Volatilities of Refractory Materials. A vast number of experiments were made and many interesting and important results obtained. We give here a few of the most striking conclusions:

"For materials boiling above iron saturated with carbon (3500° C.), a series of boiling points were estimated on a triple basis of reference (1) to the curves with iron for equal (atomic) amounts of material, (2) fractional distillation and (3) position of deposition at negative crater. The boiling points of this series are as follows:

|                                 | Deg. C. |
|---------------------------------|---------|
| Iron Saturated with Carbon..... | 3500    |
| Silica.....                     | 3500    |
| Palladium.....                  | 3600    |
| Carbon.....                     | 3700    |

#### DISCHARGE CHARACTERISTICS OF A DRY CELL

Mr. C. A. GILLINGHAM of the National Carbon Company contributed a paper on discharge characteristics of a certain make of dry cell. Tests were made on the well known No. 6 dry cell (2.5 x 6 in.) by discharging to given end-point voltages (1) through constant resistances, (2) at constant current through varying re-

sistances, and (3) through Mazda lamps. The results were illustrated by numerous charts and tables.

#### SOCIETY INVESTS IN LIBERTY BONDS

Following Mr. Gallingham's paper the Directors' meeting was held at which it was unanimously voted to invest \$2000 of the Society's funds in the Fourth Liberty Bonds. This brings the Society's total investment in Liberty Bonds to \$8000. Mr. C. G. Schluederberg, chairman of the Membership Committee, reported 1920 members on the Society's roster. The Board decided to hold the spring meeting at New York City and the 1919 fall meeting at Chicago in conjunction with the Fifth National Exposition of Chemical Industries.

The evening session, Sept. 30, was devoted to moving picture demonstration of the Fixation of Atmospheric Nitrogen at Niagara Falls, Power Development and Electrochemical Industries of the Shawinigan Water & Power Company and the Triplex Steel Process at South Chicago. The pictures were exceptionally clear and brought forth much favorable comment. At the South Chicago plant there will be ten 25-ton electric furnaces, forming the third step in the triplex process. The capacity, upon completion, will be 50,000 tons of triplex steel per month. The cost is about that of present open-hearth steel, according to Professor Richards.

#### SYMPOSIUM ON ELECTROCHEMISTRY AFTER THE WAR

President Tone had arranged for an all-day symposium on Tuesday. This proved a great success; many of the papers were of exceptional merit and the discussions had to be frequently curtailed on account of pressure of time. In his introductory remarks, Mr. Tone referred to the remarkable progress that electrochemistry has experienced within the last few years and emphasized that it was not too early to consider seriously what is to become of the various electrochemical industries after the War.

#### THE FUTURE OF ELECTROLYTIC CHLORINE

Mr. A. H. HOOKER of Niagara Falls reviewed the progress of the chlorine and alkali industry within the last generation and commented at length upon the present world-wide importance of chlorine gas and its numerous compounds: Chlorine for phosgene, for chlorpicrin, for mustard gas, for bleach, chlorine as a cloud gas and for smoke screens, chlorine as a disinfectant and sterilizer, chlorine for chlorbenzol explosives, picric acid and parazol, for chloroform for aeroplane dope and for fire extinguishers. Likewise, England, France, Italy and Japan, to say nothing of Germany, have all materially increased their chlorine output during the War. There will be a large surplus of chlorine after the War at the present rate of production and what is really needed are new uses against which chlorine can be charged at a fair operating price. "Our research departments and universities should give every encouragement to a larger development of our permanent chlorine industry, since the maintenance of these chlorine-producing plants with a constant market is as important to the Government as the maintenance of reserve plants for the manufacture of sulphuric acid, the fixation of nitrogen or any other basic munitions."

#### COMMERCIAL USES OF CHLORINE

Dr. V. R. KOKATNUR, of the Niagara Alkali Company, was the second speaker in the symposium. He enu-

merated and described in detail the present and most probable future commercial uses of chlorine. His paper was very highly appreciated and conceded to be a most valuable compendium. A full publication of Dr. Kokatnur's paper will be made in a later issue. The success of the electrolytic alkali industry depends not so much upon the profits obtained from caustic as upon those from chlorine. Hence chlorine is to be considered the primary product.

#### THE WAR AND THE NITROGEN INDUSTRY

Dr. W. S. LANDIS, of the American Cyanamid Company, presented the after-the-war possibilities of the nitrogen-fixation industries. The commercial production of air nitrates is but ten years old. In 1903 the world's production of nitrogen in the form of Chilean nitrate and of sulphate of ammonia was equivalent to only 503,000 short tons of nitrogen. In 1914, at the outbreak of the European War, the producing rate of the world in short tons of chemical nitrogen was as follows: nitrate of soda, 425,000; sulphate of ammonia, 285,000; arc process products, 11,000; cyanamid products, 31,000; synthetic ammonia and miscellaneous, 12,000; total: 764,000 tons. The estimated total for 1919 is 1,341,000 tons of which cyanamid products contribute 360,000 tons. The total production of nitrogen in the United States alone in 1919 is estimated at 509,000 tons, or 38 per cent of the world's output. The United States producing rate in the early part of 1919 will therefore be approximately three times that at the outbreak of the War. At the close of the War our consumption will probably be less than 50 per cent of the production. To take care of the excess nitrogen products, the fertilizer industry offers the most hopeful field of investigation. The Cyanamid company has appreciated the situation and has developed a new, highly concentrated fertilizer containing some 65 per cent of plant food, compared to 12 per cent and 20 per cent, the former standards. The cost in handling and freight will therefore be greatly reduced and the narrow strip of fertilizer-consuming farms along our coast, will be extended many miles inland. When fertilizer can be profitably put into the Middle West the consumption will be enormous. It would take the stimulating effect of several wars to build sufficient fixation plants to over-produce in such a market.

In the discussion of Dr. Landis' paper, Mr. C. G. ARWATER suggested that hereafter the modified Haber process be referred to as the "General Chemical Company's Synthetic Ammonia Process." The introduction of concentrated fertilizers which could be cheaply transported to our Central and Middle-West farms deserves every bit of encouragement. Mr. E. KILBURN SCOTT estimated the world's total arc processes for nitrogen fixation at 635,000 horsepower, and on the basis of 60 to 80 grams per kilowatt-hour an equivalent of 50,000 tons of arc-process nitrogen for 1919, and not 15,000 as estimated by Dr. Landis.

#### THE ELECTRIC FURNACE AFTER THE WAR

Mr. F. A. J. FITZGERALD, of Niagara Falls, talked on the electric furnace after the War. Some of the electric furnaces will undoubtedly go out of business. But many of the types will survive the strain of the reconstruction period. The induction-type furnace did not

develop as was expected. The advantage of dispensing with electrodes cannot be overlooked. Although the induction furnace is at present contending with lining and design troubles it seems most reasonable to expect that some modification of the Hering furnace will win out eventually. In general, the electric furnace situation after the war will be very largely dependent upon water-power development. Government ownership of water power is the most serious menace to the electric-furnace industry. It seems that the hour is rapidly approaching when it must be decided whether "the people exist for the state, or the state exists for the people."

In the discussion, Mr. ROBERT TURNBULL, of Welland, Ontario, agreed with Mr. Fitzgerald that water powers ought not to be in the hands of the government. Plants can be ordered shut down at any time and there is no redress. Mr. C. H. VOM BAUR, electric furnace engineer, of New York, maintained that as far as the electric steel industry was concerned, the future was well assured. Not only on account of the high quality of the electric steel as compared with ordinary steel, but also as a matter of economy, the electric furnace will survive and prosper. Many plants will introduce the duplex process, others will use the electric furnace for keeping ferromanganese molten and still others will maintain the electric furnace for melting scrap. At  $\frac{1}{2}$  cent per kilowatt-hour it is cheaper to melt scrap in an electric furnace than in any other. Mr. C. G. ATWATER brought up the question of power rates. Mr. P. J. KRUESI, of Chattanooga, Tenn., inquired as to the furnace patent situation after the War and hinted that difficulties might arise. Mr. E. KILBURN SCOTT cited the experience of England in municipal ownership of power plants. The outcome was most unfortunate. The biggest unit in England to-day is 15,000 kw. whereas in the States units of 60,000 kw. were not uncommon. Mr. HENRY E. RANDALL, lately with the Shawinigan Water and Power Company, discussed power rates and mentioned that the consumption of electric power in Ontario was 2.5 times greater per capita than in any other community. By cutting the rates in half the income from power users increased from \$700,000 up to \$840,000, whereas the returns on lighting dropped from \$300,000 down to \$250,000. However, the total income increased by \$90,000.

#### THE FUTURE OF ELECTRIC STEEL

Dr. JOHN A. MATHEWS, President and General Manager of the Holcomb Steel Company, contributed a paper on the Future of Electric Steel. "We are in our thirteenth year in the manufacture of electric steel. In automobile and airplane construction, and in many other ways, electric steel has given a splendid account of itself. Electric steel may well be called 'super steel.' It has had the indirect effect of stimulating better production on the part of open-hearth and Bessemer steel makers, and thus it may be considered as a beneficial acquisition to the entire steel industry. Easily oxidizing metals, like vanadium, chromium and manganese are readily handled in the electric furnace, and hence less of them need be had to use a final minimum content in the steel. Less of the oxides of these metals will be produced in the steel and therefore less of these oxides need be removed. Sulphur and phosphorus can be readily eliminated. With the electric furnace, alloy steels are made in the furnace itself rather than in the ladle, and

in this way there is better opportunity for increasing the solution, diffusion and homogeneity in the product. The field for electric steel in the future is a very promising one and when its merits are fully recognized new additional uses for it will be found."

Dr. MATHEWS' paper was discussed by Messrs. RICHARDS, EMERSON, SCHLUEDERBERG, DARLINGTON, MILLER, SCOTT and TURNBULL. Dr. RICHARDS referred to the manufacture of armor plate. Fifty per cent of the alloy goes back to the furnace and practically all of the chromium is lost on remelting. If electric furnaces could be introduced in the manufacture of armor plate a great saving would be brought about since practically all the chromium would be retained by the alloy. All attempts to convince the authorities of the advantages of the electric method have been of no avail. Electric steel production often requires less skilled labor than does the open-hearth or crucible process. Mr. DWIGHT D. MILLER prophesied that the electric annealing furnace would surely continue to prosper after the War on account of its numerous advantages and economies over older methods: electric annealing is automatic and absolutely reliable. Conditions of temperature and time can be most closely controlled and readily duplicated. For example, in the heat-treatment of anchor chain, all links receives similar treatment. Mr. Miller also believed that electric brass-melting had come to stay, as it is a cheaper and better process. Mr. KILBURN SCOTT mentioned that the electric furnace had been the salvation of the aeroplane industry in England. Furthermore, electric furnace smelting of scrap right outside of London had saved useless freight trips to and from Sheffield.

#### ELECTRIC PIG IRON AFTER THE WAR

Mr. ROBERT TURNBULL, of Welland, Ontario, gave a highly interesting presentation on Electric Pig Iron After the War. This industry is still in its infancy. A year ago the total output of Canada was only 900 tons of electric pig per month. To-day this output in Canada has attained over 2500 tons, and by the latter part of November the production will be between 4000 and 4500 tons per month. The consumption of electrodes is about 21 pounds per gross ton of iron. The power consumption aggregates a little over 500 kw.-hr. per gross ton. The average analysis of 25 consecutive heats is as follows: Si, 1.16 per cent; S, 0.014; P, 0.020; Mn, 0.70; and C, 3.19. The desired silicon is 1.00 to 1.25 per cent. At present this low-phosphorus pig iron is made from scrap shell turnings. After the War this supply of scrap will cease. However, similar scrap will undoubtedly be available, since it is very probable that the open-hearth will discontinue the use of turnings as a matter of economy and expediency as soon as it can obtain its supply in heavy-melting scrap. If, however, the quantity of turnings available is insufficient to meet the demands of the electric pig industry, it is probable that the present furnaces would be used for smelting iron ore. About 1400 kw.-hr. is required to produce one gross ton of pig iron from a mixture of 50 per cent ore and 50 per cent turnings. The quality of electric pig is superior to that of ordinary pig and this in itself will very likely insure a steady demand for electric pig iron by high grade steel manufacturers after the War.

## THE POWER SITUATION AFTER THE WAR

Mr. C. A. WINDER, of the General Electric Company, spoke at length on that most vital of all questions, The Power Situation After the War. We have too long looked upon power production as a simple problem, an economic factor that would gyrate nimbly to the tune of "supply and demand." No definite action has been obtained from Washington simply because no comprehensive demand has been made upon the legislative bodies there. Water turbines have an efficiency of approximately 90 per cent compared with 8 per cent of the reciprocating engine, 17 per cent of the gas and oil engines and 21 per cent of the steam turbine. The super-steam-station idea, locating power plants of a half million horsepower at the coal mines, is as "fantastic and extravagant as a caliph's dream." A half million horsepower plant would require 55,000 cubic feet of water per second or considerably more than the entire Ohio river during its normal period. Water-power is the only economic power and "there is no reason why water power industry should not develop quickly to a size and importance far beyond the fondest dreams of the present day pioneer."

Mr. HENRY E. RANDALL in discussion pointed out that if all the water power in the United States were developed it would not take care of the present day demand. A large consumer of electric power is the storage battery and a battery of about half the weight of the present would find a very big market. The use of peak power is rapidly increasing in Canada and has resulted in a much higher general load factor. Dr. RICHARDS thought that super-steam stations ought not be discouraged on account of the question of cooling water supply. Although the water near mines is acid, acid-proof condensers could be used. Mr. KILBURN SCOTT said that in England it would be considered best practice to locate the super-steam stations at the water-side and to carry the coal in pipe lines to the stations. Mr. SCHLUEDEBERG, of the Westinghouse Company, referred to the large steam plants being built at coal mines in Pennsylvania. Mr. Winder added that if the government would act favorably toward water-power development, private interest would obtain capital for such developments easier.

## SURPLUS ELECTRIC POWER AFTER THE WAR

Dr. JOHN W. BECKMAN, of San Francisco, suggested in his paper two outlets for surplus electric power after the war. "Two industries, both of them basic and both of them producing products essential to mankind, appear as suitable life savers to the electric developments after the War." One of them is the iron and steel industry and the other is the fertilizer industry. A very important electro-metallurgical development awaiting a successful solution is the direct manufacture of steel from iron ore. We have already reached forward toward this goal; in the electric shaft-furnace pig iron is now produced, known as steel pig iron. The next step will be the finished steel. The other industry which would serve to consume power after the War is the fertilizer industry. Two of the important ingredients in a fertilizer are nitrogen and phosphorus. The nitrogen-fixation industry will continue, particularly if encouraged by the Government. It is an industry essential

in times of peace as well as in war. The phosphorus in our phosphate rock, distributed through many of our states, can be made completely water-soluble by electrical methods, whereas by the old sulphuric acid method, only a small per cent of this phosphorus is rendered water-soluble.

Discussing Dr. Beckman's paper, Dr. LANDIS, of the Cyanamid company, was of the belief that eventually there would be an international committee to guide and control the development of industries. The application of fertilizers might well be regulated or ordered by the governments. The same applies to the power developments. Everything points toward a government control of industries. Probably the railroads, telephones and other utilities will never go back to the old system after the War. Mr. L. E. SAUNDERS, of the Norton Company, called attention to the new interconnecting of power plants at Niagara Falls resulting eventually in much lower rates. Mr. ACHESON SMITH, of Niagara Falls, pointed out that the fertilizer industry was of the elastic type. When food prices are high, farmers have large incomes and gladly buy fertilizers; when food prices are low farmers will be forced to buy fertilizers.

THE GOVERNMENT AND THE TECHNICAL MAN  
AFTER THE WAR

Dr. F. A. LIDBURY, in his usual highly entertaining style, submitted his reflections on the government and the technical man after the War. It appears most probable that a number of the scientific boards and committees appointed during the War will continue after peace is signed. Furthermore, the present close working of men of pure science with those who have specialized in applied industry and engineering has proved so vastly beneficial to all parties concerned that "one may feel quite certain in hazarding the conviction that the two fields will never fall so far apart as before, and that industry will be the gainer to the extent that it permanently receives the originality of view and boldness of conception of the pure scientist."

Mr. H. B. COHO, of the United Lead Company, in discussing Dr. Lidbury's paper emphasized that the underlying, fundamental question for us to answer is: "Are we as technical men willing to take on the responsibility of government? Are we ready to shoulder the duties of a governmental office?"

Mr. L. E. SAUNDERS offered the following two resolutions: (1) That the American Electrochemical Society is in full accord with the policies of the United States Shipping Board and will gladly cooperate in every way. (2) That the Public Relations Committee of the Society investigate the pros and cons of government ownership of water power.

## RESEARCH AFTER THE WAR

Colonel BANCROFT received a well deserved ovation as he arose to present his views on research after the War. He heads the Electrochemical Committee of the National Research Council. "Remarkable changes have been brought about by the War. This applies to all branches of chemistry. In organic chemistry the whole situation has been changed; we have learned to consider yields. The application of physical-chemical methods to organic chemistry offers great possibilities.

Some of the poisons recently developed, such as the arsenical and prussic acid compounds, might become valuable insecticides. New organic gases that are now used to kill men might, after the war, be used to kill bugs. For many years after Sabatier's research on catalytic agents very little progress was made along these lines in organic chemistry. During the last few years, however, various catalytic agents have been used for making war gases and other compounds. We are just beginning to realize the vast possibilities. The new charcoal catalyst is better than any we made before. We are bound to find extended uses for it. In the production of ammonia a number of catalysts have been found which will surely be useful after the War. A completely new field of scientific research is bound to open up. How is this research going to be carried out? The National Research Council is encouraging the scheme whereby each industry will have its research laboratory, as for instance that of the American Cannery Association. It will also be important that the universities have research laboratories where the scientific basis of our industries could be investigated."

In the discussion, Dr. LANDIS suggested that handbooks include in the description of processes the yields of the products obtained.

#### COÖPERATIVE RESEARCH LABORATORIES

Dr. C. E. K. MEES, of the Eastman Kodak Company, spoke at length on coöperative research laboratories, their advantages and limitations. He pointed out that Great Britain had already inaugurated the scheme of establishing coöperative research laboratories and that results so far were very encouraging. The English Government subscribes one-half toward the cost and maintenance and the other half is covered by individual subscription from each member of the industry. These laboratories are very often operated in connection with the universities. There are five distinct types of problems that can be covered by a research laboratory: (1) fundamental research. (2) raw materials; new sources; new methods of working up. (3) products. (4) processes. (5) applications. Research of the types 1, 2 and 5 interests all industries. They are external to the works. However, numbers 3 and 4 are internal and are not suitable for coöperative research; they involve secret, competitive methods. The British Government therefore assumed that everybody would be interested in fundamental research when inaugurating the system. At the Rochester laboratory of the Eastman Kodak Company about \$30,000 a year is expended on fundamental research. "In one case we worked for five years before we found out what we were looking for!" But the new by-products found and developed during this time made the pure research a paying thing. There is also a good deal of advertising value in having a "tame research man" go to various society meetings and talk on the laboratory's pure research. As a result of his high-toned talk you will get orders. A research laboratory in a small concern can often make more money than a similar laboratory of a large corporation. In the latter there is too much red tape, whereas the small laboratory can go right ahead and make the new article and sell it to the public. What this country needs are National Research Laboratories, for example a National Alloys Research Laboratory to which all inter-

ested industries would subscribe. There are very few industries not interested in alloys. Similarly, let us have a Fuel Research Laboratory, a Metal-Cutting Research Laboratory—about a dozen national research laboratories of this type.

In discussing Dr. Mees' remarks, Mr. SCHLUEDEBERG suggested that some scheme be advanced for the coördination and coöperation of the various research laboratories now operating in this country. Thus much duplication of effort could be avoided and no doubt better and more rapid progress in research made. Dr. FINK referred to the deplorable condition of our patent laws and said that much of the success of the research laboratories depends upon proper protection and recognition of original products and processes. Dr. R. E. ZIMMERMANN, of the Research Laboratory of the American Sheet and Tin Plate Company, discussed the value and importance of research on the standardization of products. Mr. MOTT pointed out the dire need in this country of handbooks covering the various industries, handbooks such as are found in Germany. Dr. RICHARDS suggested that it would be well worth while studying the history of the Swedish Iron Masters' association in connection with establishing coöperative research laboratories in this country. Dr. M. G. WEBER called attention to the fact that very often new and valuable processes were not made public properly. He favored the appointment of a committee whose duty it would be to bring to the attention of the industries and its members the importance of a new process or product. Mr. C. P. MADSEN commented favorably upon the Patent Approval Association that is now working in conjunction with the National Research Council. Mr. KILBURN SCOTT announced that England was setting up a large research laboratory that was practically a duplicate of the Mellon Institute at Pittsburgh. What is needed in England and in fact in all countries is a committee that would look after the interests of "the poor inventor." In closing the discussion, Dr. MEES conceded that the patent question is a very important one and that some years ago he had written a paper outlining a Utopian Patent System—but being afraid of his lawyer friends, he never published it.

#### TARIFF PROBLEMS IN THE ELECTROCHEMICAL INDUSTRIES

Dr. GRINNELL JONES, chemist of the United States Tariff Commission, presented a paper on the tariff problems in the electrochemical industries. The Tariff Commission is trying to gather information which will be of value after the War. In the chlorine and caustic soda industry protective tariff legislation, 25 years ago, helped the development of the industry. Chemically we get the two products in equivalent amounts, but commercially the demand for caustic exceeds that for chlorine. We have therefore had large imports of bleaching powder. Between 1909 and 1913, 40,000 tons of bleaching powder was imported annually. In 1909, 58,000 tons was produced in the United States and in 1913, 155,000 tons. Our imports of bleaching powder in 1916 dropped to 16,000 tons, in 1917 to 33 tons and in 1918 to 2 tons. Our exports in 1913 will probably total 6500 tons bleaching powder; to this must be added the chlorine in form of poison gases. In 1914 we exported 43,663 tons of electrolytic soda and in 1917, 126,570 tons. What are we going to do with the excess chlorine after

the War? Not much help is to be expected from the dye industry since this consumes only about 2 per cent of the output. The carbon tetrachloride industry consumes but one per cent of the output. Chlorine manufacturers and chlorine consumers must keep the Tariff Commission closely advised as to production, consumption and new outlets.

In the abrasive division of the tariff laws there is at present considerable discrepancy in the duties imposed on the various products and raw materials. Grindstones and hones are on the free list and no distinction made whether composed of natural or artificial abrasives. On the other hand emery stones are taxed. Better classification is needed. The demand for artificial abrasives is greater than the available water power. About two-thirds of the artificial abrasives are now imported from Canada. Shall we put a duty on Canadian abrasives? We are now producing large quantities of phosphorus. And what is to become of the potash industry after the War? As regards the nitrogen-fixation industry, is the Government going to levy a protective duty and protect itself? It is necessary to collect in advance information in order to draw up proper tariff legislation, and the coöperation of the men of the industries is absolutely essential.

Mr. L. E. SAUNDERS, of the Norton Company, did not fully agree with Dr. Jones' statements relative to the abrasive situation and maintained that the shortage of natural abrasives had been fully met by the manufacturers of the artificial products. There is at present even an overproduction of artificial abrasives.

In bringing the symposium to a close, President Tone expressed his and the Society's appreciation for the highly interesting papers contributed and hoped that the serious problems that had been brought before the Society would give rise to further debates and discussions and future meetings.

#### THE NORTHRUP HIGH-FREQUENCY FURNACE

The main part of the Tuesday evening session was devoted to the new Northrup furnace. Dr. E. F. NORTHRUP, of Princeton University, gave a highly interesting address describing in detail the construction, development and operation of his latest type of induction furnace. A preliminary announcement and description of the Northrup furnace appeared in the Aug. 1, 1918, number of this journal. The experiments were started about two years ago for the Ajax Metal Company, of Philadelphia. Mr. G. H. Clamer, vice-president of the company, deserves much credit and appreciation for his support of the enterprise and his broad vision. Dr. Northrup also paid a graceful compliment to his mother who had ever taught him to have high ideals. It was a high ideal that formed the original conception of the new high-frequency induction furnace: "Heat the charge or its container without heating anything else."

The resistance type of furnace could never realize this ideal. The best resistance wire will stand but 1282 deg. C. and a furnace built of this wire would with difficulty melt copper (1082 deg. C.). For example, when the heat of this resistance furnace has reached 1081 deg. there is a temperature gradient inwards of 201 deg. and outwards to the room of 1282 deg. If we were to try to melt an alloy, of melting point 1282 deg., the efficiency of the furnace would be zero. Therefore for

high efficiencies the heat must be generated within the container. The high-frequency induction furnace is the solution of the problem. In order to attain the very high frequencies required, Dr. Northrup developed a high-frequency oscillatory discharge gap: there are three Acheson graphite electrodes surrounded by an atmosphere of alcohol. Eventually with the further development of the Alexanderson high-frequency alternator this discharge gap will be dispensed with. It is planned to build alternators of 1000-kw. capacity, whereas the largest units at present are rated at 200-kw. and 2300 cycles. In the present small type Northrup furnace brass can be melted at the surprising rate of 45 pounds in 35 minutes. Nickel is readily fused. In the small furnace, equipped with the oscillatory discharge gap, the efficiencies are around 50 per cent whereas eventually with an Alexanderson alternator efficiencies of 90 to 93 per cent are more than probable. One of the proposed large-scale adaptations of the new furnace is for the retention of the heat in the steel ladle. In this case the ampere turns would be embedded in the refractory lining of the ladle. In conclusion Dr. Northrup referred briefly to his "focus inductor" furnace in which any temperature that a magnesia crucible will stand can be attained. Messrs. SCOTT, BRALEY, CUMMINS, BRADLEY, ROUSH and MOTT participated in the discussion.

#### THE NORTHRUP FURNACE IN OPERATION

Dr. Northrup's address of Tuesday evening was supplemented by a personal inspection of the furnace at the Pyroelectric Instrument Company's laboratory at Trenton. The members of the Society left the Traymore early Wednesday morning arriving at Trenton about eleven o'clock. Dr. Northrup demonstrated at his laboratory how easily nickel could be melted in the high-frequency furnace and in a second experiment, roller-bearing rings were brought up to the desired quenching temperature in a very few minutes. In the latter case no crucible was required: the energy was focused directly onto the rings. There were also demonstrations of the high-frequency arc and focus inductor. The visit to the Pyroelectric laboratory was one of the most enjoyable features of the meeting. It was generally conceded that the high-frequency furnace was the greatest advance in electric-furnace design since the days of Moissan.

#### Prices of Sulphuric and Nitric Acids

On Oct. 4, the War Industries Board modified the division made on September 26 in evaluating sulphuric acid, whereby 92 per cent  $\text{H}_2\text{SO}_4$  instead of 66 deg. B. (93.19 per cent) shall be the division point. Acid below 92 per cent  $\text{H}_2\text{SO}_4$  shall be evaluated according to its equivalent of 60 deg. B. acid at the price of \$16.00 per ton; and acid above 92 per cent  $\text{H}_2\text{SO}_4$ , on its equivalent of 66 deg. B. at \$25.00 per ton. See CHEMICAL AND METALLURGICAL ENGINEERING, page 571, for first announcement.

On Oct. 3, the statement of 8½c. per lb. as the flat rate for 42 deg. B. nitric acid was further amplified to read 67.18 per cent. This makes the price of nitric acid 2.53c. per ton unit, which is \$170 per ton for 67.18 per cent acid. This price applies to mixed acid also, in which  $\text{H}_2\text{SO}_4$  shall be 0.268c. per ton unit.

## The Use of Micro-organisms in Chemical Industry

**Yeasts, Moulds and Bacteria Important Organic Chemicals Widely Used in Industry — Further Industrial Applications and Developments Await Research — Some of the Possibilities**

BY ERNEST G. GENOUD

**T**HE MICRO-ORGANISMS to which we refer are yeasts, moulds and bacteria. They are of the nature of plants, and, like their vegetable colleagues most of them require for their growth and development carbon, nitrogen, water, oxygen, phosphorus and calcium. Many of them, like other plants and unlike animals, can metabolize nitrogen in the form of simple soluble salts instead of complex proteid substances. Others, again, find their principal nutriment in proteins.

They are classified according to their external forms. In physical appearance but not in any biological sense we may say that yeasts resemble microscopic vines, moulds resemble moss, and bacteria, rods and spheres. Their functions are of almost infinite variety, and there is a vast deal about them that is not known.

In a chemical sense the most familiar of all are the yeasts, or more particularly the saccharomyces, which split fermentable sugars into ethyl alcohol and carbon dioxide. They secrete especially two enzymes of which one goes forth from the yeast cells and effects a transformation of some sugars from an unfermentable into a fermentable organization. This does not consist in splitting them into single carbon chains. Some monosaccharides are not fermentable while some di- and trisaccharides are. The second enzyme remains in the yeast cell, and as the solution of fermentable sugars enters the walls the desired reaction takes place.

### NITROGEN ESSENTIAL TO FERMENTATION BY YEAST

If a culture of yeast is introduced into a solution of pure sugar and pure water, the ensuing fermentation will be very incomplete, for the obvious reason that there is no nutriment present for the yeast, so that its growth and progress are halted. It must have soluble nitrogen salts or compounds, and in the fermentation for beer or alcohol from grain or starch this is found in asparagin and other amido acids which are present in all young sprouts and especially in the barley sprouts of the malt. The primary purpose of the malt, as is well known, is to provide the enzyme diastase to convert the starch to sugar. Certain moulds may take the place of malt in this process. Our readers may recall such a mould introduced by Dr. Takamine from Japan which was a culture, as we recall it, used in the production of sake from rice in that country. In France there is now a great industrial alcohol plant using potatoes for starch, and there a mould instead of barley malt is employed. When sugar is the initial material instead of starch, as in the case of grapes or molasses, no malt or diastatic agent is required in fermentation.

We shall not address ourselves to the main process of fermenting sugar to alcohol and CO<sub>2</sub>, which is familiar to all chemists, but consider rather some of the by-products which are always present, and are found in

varying proportions. These are iso-butyl and amyl alcohol, glycerol, succinic acid, acetaldehyde, acetic acid and various esters. Just how iso-butyl alcohol is formed as a product of yeast fermentation is not known. We shall not consider the subject at length because butyl alcohol is produced in great quantities in one of the biological processes for making acetone, and again butyric acid is obtained direct from starch by a special bacillus, so that if an industrial demand for either the acid or the alcohol should arise it may be met in abundant quantity. Amyl alcohol on the other hand is called for with a loud cry, and fortunately it is known that its presence is due to the fermentation of proteid substances and not to that of sugar. It is sorely needed for the production of amyl acetate as a solvent for nitro-cellulose and, to a less extent, for synthetic fruit syrups and perfumes. And if it ever should become cheap enough, the industrial steps from amyl alcohol to isoprene and from isoprene to synthetic rubber are nearly in sight. There is, therefore, every reason for the incidence of research upon the problem of cheap production in large quantities of this once detested and injurious ingredient of potable liquors. When we get to know beans as well as Dr. Theodore B. Wagner and certain other chemists know corn, and even before that, it may become a profitable enterprise to study the fermentation of proteins to fusel oil along with the starch to ethyl alcohol. Since beets are grown with profit in the beet sugar industry it may be that beans will be grown with profit to produce ethyl alcohol together with large quantities of amyl alcohol. The subject is full of interest. In present day fermentation it sometimes happens that iso-butyl and amyl alcohols are found to the extent of 3 to 1 per cent in crude distilled spirits.

### GLYCEROL PRODUCED IN SMALL QUANTITIES

Glycerol seldom runs above one-third of one per cent of the fermented mash, and it has not been found economical to separate it thus far, notwithstanding the war's demands for glycerine for nitrating purposes. How it is produced is not known; that is, there is less known of it than there is of the production of amyl alcohol by fermentation. Whether under post-war conditions there will be any such demand for glycerine as there is at present is open to question. Whether also the road to biologically produced glycerine is too long to be undertaken in the face of the immediate demand is also a subject for discussion. Perhaps the matter is already in hand at American University. According to reports lately received the Germans have developed a yeast of which the cells contain as much as 40 per cent of fat in the dry substance instead of about 5 per cent which is the usual proportion. It is said that they have been cultivating this in quantity and removing the glycerine by saponification, but we do not guarantee the truth of this statement.

The more specific production of succinic acid and the innumerable esters are also subjects for research in less crowded hours, while the steps from ethyl alcohol to acetic acid are known and studied, and are in good hands.

At the present stage of the art it may be said that the development of excessive undesired by-products in the fermentation for ethyl alcohol is usually due to

infected yeast and occasionally to overmuch foaming of the beer and the consequent oxidation that ensues.

#### CONSTRUCTIVE AND DESTRUCTIVE METABOLISM OF YEAST

In the production of alcohol, whether for drink or industrial uses there is always a great excess of yeast grown, because of the rapidity with which the cells reproduce. Under favorable environment the plant thrives lustily and while the manufacturer is always careful of the comparatively small amount that goes into every fresh vat, he has a great quantity left over after every fermentation.

Here is waste, a serious waste, and one that should be avoided. Usually it is messy stuff and like most good things that we discard, it does not behave very well under such treatment. Being rich in protein it is a valuable food. Properly treated it is good cattle fodder, and still more carefully treated it is excellent human food, and is considerably used in England for this purpose. The preparation is interesting: In the building up of yeast cells, as we have already observed the nitrogenous constituents may begin with very simple ammonium salts. In the metabolism of the plant these ascend in steps of increasing complexity to amido acids, peptones and albumoses to insoluble albumen. Now, if the yeast is washed free of all wort and mash and is left to stand wet or in pure water, it proceeds, having no nutriment, to consume itself by a process of auto-digestion, induced by the enzyme endo-tryptase. At the optimum temperature of about 40 deg. C. the insoluble albumen is broken up and the direct reverse of the metabolic process takes place. There occurs a breaking down, in consecutive order, of insoluble albumen to albumoses, peptones, amido acids and, finally, ammonia.

#### VEGETARIAN "BEEF EXTRACT"

This is not putrefaction, and unless the yeast is infected putrefaction will not take place. By halting the process at a point at which the peptones and amido acids predominate, and sterilizing at about 70 deg. C. to destroy the enzymes, the product remains stable. For convenience of transportation and use it is then concentrated and the result is a food which is fully equal to beef extract, containing up to 35 per cent of peptones and amido acids. If properly made it is very agreeable to the taste and is not to be distinguished from beef extract save by very astute analysis. It has reached an important industrial stage in England and the yeast product made in this manner is sold as vegetable extract under the trade name of Vegex. It enables the vegetarian to have his beef juice without the passing of the steer, but its consumption is by no means limited to vegetarians. The amido acids are excellent digestive stimulants.

For cattle feed the yeast is washed and dried. Being relatively rich in nitrogen, potash and phosphorus, it should also serve well as a fertilizer.

#### BACILLI PRODUCE ORGANIC ACIDS

The most widely known industrial use of moulds is in the production of cheese, to which we shall give but passing mention and proceed to consider bacteria which are divided into three classes, according to their external form. They are of almost endless variety.

They are the smallest forms of plant life, some being not over  $2\mu$  in length. The spirillum, on the other hand, which is also a variety of bacteria, grows up to the length of 12 to  $15\mu$ . The three principal types are the bacilli which are rods somewhat of the shape of minute Frankfurter sausages, the cocci which are spherical, and the spirilla which are corkscrew shaped.

The lactic acid bacillus has the function of converting almost any starch into sugar and the sugar into lactic acid, and it is impossible to isolate the sugars during the process. It is used by manufacturers of compressed yeast, who look for the greatest production of yeast rather than of alcohol, because it decomposes the complex albumen molecule and brings it down to amido acids, at which point the yeast is much more able to assimilate its nitrogen. If the demand for lactic acid should increase there should be no difficulty in meeting it.

There is also a butyric acid bacillus which attacks starch, sugar and lactic acid and produces the ill-smelling butyric acid. And in recent years bacteria have been discovered which produce acetone from carbohydrates, along with a greater quantity of butyl alcohol as a by-product.

The cocci and spirilla are more generally known from their pathogenic representatives, although there is no known rule or relation between the shape and size of a micro-organism and its function.

#### SOME FUTURE PROBLEMS

We have considered a few of the bodies known to be produced and it seems as though properly directed research might not only add to the sum of knowledge but enhance the national estate as well. Let us therefore engage the imagination a little and see what possibilities beckon us over the fire-fly swamps where the roads have not been laid out as yet. If we have yeast to make ethyl alcohol in quantity from sugar and starch and amyl alcohol inadequately from proteid substances, and a bacillus for butyl alcohol from starch, why should we not find or develop a culture for propyl alcohol, and more especially for the production of methyl alcohol? We separate cetyl alcohol,  $C_{18}H_{37}OH$ , from spermaceti, and melissyl alcohol,  $C_{26}H_{53}OH$ , from beeswax. The higher alcohols are excellent waxes; why not try to find a micro-organism to make them in tubs? These are likely to be cheap processes if they are started right.

Again there is the fermentation of cellulose to methane and hydrogen. Here is an enormous field for study. Nature does it in marshes and in the earth, so why should we not wring the secret from her and get it under control? Even the gases formed within the body are due to the fermentation of cellulose and not to that of starch or proteins. Under proper conditions we could grow our own gas, making it fresh every day, and save coal. Imagine a great vat in a prosperous village, seething away, fermenting wood-waste, garbage, old newspapers, and rubbish of every sort, and delivering methane and hydrogen into a convenient gasometer. Observation thus far seems to indicate that the cellulose is hydrolyzed to sugar by means of an enzyme and that fermentation proceeds to  $CH_4$  and  $H_2$ , while the lower fatty acids arise as by-products.

# Reinforced Concrete versus Salt, Brine and Sea-Water\*

An Account Citing Many Examples of Failures in Reinforced Concrete and Showing the Cause to Be Due to Electrolytic Corrosion of Reinforcements

By HENRY JERMAIN MAUDE CREIGHTON

ON ACCOUNT of the rapidity and cheapness of construction, at present attention is focused on the reinforced concrete ship. A large reinforced concrete ship has just been launched at a Pacific port in the United States, where others are in the process of construction; and it is believed that such ships will be built on a large scale. Although the durability of the reinforced concrete ship is still an undetermined factor, the claim is made that it would exceed the term of the war. In a large measure the durability of reinforced concrete ships will depend upon the action of the sea-water on the concrete and on the iron reinforcements.

During the past few years there has been considerable discussion regarding the durability of concrete, and there exists a certain amount of disagreement on the subject. There appeared in *Engineering News* of April 4, 1912, wherein is published a report of the American Society for Testing Materials' meeting, the following sentence: "The report of the waterproofing committee brought about some excited discussions, during which several persons affirmed their belief in the imperishability of concrete and protested against any hint of any other possibility." However, though "it is no doubt true that many diseases can be cured by a practitioner who strenuously denies their existence and thus encourages the patient to resist and overcome them, it can hardly be expected that defective concrete walls or disintegrating piers can be strengthened by 'absent treatment,' however vigorous be the denial of the injury or however prominent the denier." It is much better to look facts in the face and attempt to find a remedy.

## REACTION BETWEEN THE ALKALI SALTS AND THE CEMENT SILICATES

Sea-water, one of the agents which brings about the disintegration of concrete, attracted the attention of users of cement soon after it was first employed in marine construction. Although a great deal of non-reinforced concrete has withstood the action of the sea up to the present time, and will probably continue to do so, still some of it has failed. While the cause of this disintegration is not definitely known, Le Chatelier and others have pointed out that it can probably be ascribed to a reaction between the magnesium sulphate of the sea-water and the lime of the cement (formed during setting) and the alumina of the aluminates of the cement, with the resulting formation of magnesium hydroxide and calcium sulpho-aluminate, which crystallizes with a large number of molecules of water. Notwithstanding that the other components of sea-water have usually been supposed to have but little effect on

concrete, attention has recently been called to the fact that both sodium chloride and magnesium chloride rapidly react with the silicates in concrete<sup>2</sup>.

In the laboratory it is possible to destroy, almost completely, small cylinders or other forms of concrete or cement mortar by the action of solutions of various salts. The "action of the salts in alkali water and sea-water on cement" has been the subject of a lengthy investigation by Bates, Phillips and Wig, of the U. S. Bureau of Standards, and their results have been published<sup>3</sup> under the foregoing title. This investigation was undertaken in consequence of disintegration of concrete, through the action of water containing magnesium and sodium sulphates, occurring in several integration projects in some of the Western States; and for the purpose of ascertaining the action of various single and mixed salt solutions on concrete and cement. The salt solutions were allowed to percolate through hollow cement cylinders closed at one end, and it was found that any cement mortar may be destroyed if a sufficient amount of salt accumulates and crystallizes out. It was further found that, in general, chloride solutions were more effective than sulphate solutions in removing lime from concrete, but that mixed chloride and sulphate solutions were more effective than solutions of single salts.

## CRACKS DUE TO INCREASE IN VOLUME UPON RUSTING OF THE REINFORCING BARS

Several years ago the writer constructed a number of concrete blocks 3 ft. x 1 ft. x 1 ft., in which were imbedded several iron rods, and exposed them to the weather. A small quantity of sodium chloride was mixed in with the concrete. Gradually these blocks developed cracks which widened and spread as time went on; and today some of them have fallen to pieces, leaving the reinforcing rods in a badly corroded condition, while the others are badly deteriorated and iron-stained.

A striking example of the deterioration of marine reinforced concrete is to be found in Young's "Million Dollar" Pier at Atlantic City, New Jersey. At the end of two years after its completion, some of the piles commenced to disintegrate owing to the corrosion of the reinforcements. The disintegration proceeded so rapidly and the structure became so weakened, that in the winter of 1912 a large portion of the pier was swept away by a storm.

At the Key West extension of the Florida East Coast Railway, one of the steel reinforced concrete viaducts was found to have undergone extensive deterioration within two years after its completion, and in conse-

quence, since 1909, all viaducts have been constructed without reinforcements, and with a cement low in magnesium and sulphuric acid and finely ground.

According to a recent report<sup>1</sup> by J. L. Harrison, District Engineer, Hoilo, the cracking of reinforced concrete structure is markedly prevalent in the Philippine Islands. A study of this trouble has demonstrated that not a single structure showing rusted steel has been free from salt, the percentage of which varies considerably. In view of this, engineers in the Philippines have been advised that not only is the use of salt water dangerous in concrete structures, but that beach sand and beach gravel should be employed only after having been thoroughly washed with fresh water.

<sup>1</sup>Bul. of Bureau of Public Works, Oct., 1916.

The foregoing, and many other similar pieces of evidence, indicate that salt, brine, and sea-water exert a deteriorating action on concrete.

The possible causes of the deterioration of ordinary concrete are bad cement, bad aggregate, bad proportions, bad mixing, external violence, wear and tear, and the action of saline solutions; while for reinforced concrete, in addition to the foregoing causes, there are corrosion of the reinforcements either directly or by electrolysis, and cracking due to monolithic character, or possibly to stresses between the concrete and the reinforcements.

As this paper deals chiefly with the corrosion of iron reinforcements of concrete due to the action of brine, the probable reactions which occur when this metal comes in contact with a salt solution will be discussed briefly.

## CORROSION OF IRON DUE TO ELECTROLYSIS

When a piece of iron is placed in distilled water, it becomes negatively charged, since its electrolytic solution pressure (which is equal to  $1.2 \times 10^4$  atmospheres) causes atoms of the metal to enter the water as positively charged ions leaving an equivalent number of negative charges behind on the bar of metal. In spite of this large electrolytic solution pressure, only a vanishingly small quantity of the iron passes into the water in the form of ions, and consequently the metal bar receives but a correspondingly small negative charge. This is due to the fact that when a ferrous ion with its large positive charge ( $2 \times 96,500$  coulombs for every gram ion of the metal) leaves the bar of electrically neutral iron, the latter acquires a negative charge of corresponding magnitude; it therefore becomes more difficult for a second ferrous ion to enter the water, owing to the attraction between unlike charges of electricity; and it is still more difficult for a third ferrous ion to leave the metal, and so on. Consequently, very soon the negative charges upon the bar of metal become sufficient to prevent further ferrous ions entering the water, and equilibrium sets in; and, unless these negative charges are removed from the metal, no more iron can pass into the water. But suppose, now, that common salt be added to the water containing the bar of iron. On dissolving, this electrolyte largely dissociates into its ions, and it may be assumed that hydrolysis takes place although to a very limited extent, in accordance with the equation—

The concentration of these new substances being extremely small, they dissociate practically completely, and give rise to negatively charged hydroxyl ions and positively charged hydrogen ions:

The hydroxyl ions then unite with the ferrous ions that have passed into the solution from the bar of metal to form undissociated ferrous hydroxide:

which gradually precipitates as an hydrated oxide. The presence of dissolved oxygen in the solution would, of course, gradually convert the oxide and ferrous hydroxide into the corresponding ferric compounds.

The negative charges upon the bar of iron, which were in equilibrium with the ferrous ions before the addition of the sodium chloride, now attract the positively charged hydrogen ions, the electrolytic solution pressure of hydrogen being much less ( $0.9 \times 10^{-4}$  atmospheres) than that of iron and very much less than that of sodium ( $>10^4$  atmospheres), and, in consequence, hydrogen ions move toward the negatively charged iron bar, touch it and become neutral gaseous hydrogen atoms. The negative charges upon the bar being thus diminished, more iron enters the solution in the form of ferrous ions, and the foregoing process occurs again, and so on. In this way the bar of iron gradually disappears and iron oxide and hydrated oxide accumulate.

The nascent hydrogen which is produced on the bar may be absorbed by the iron; it may be oxidized by the oxygen dissolved in the solution, or it may be liberated as a gas.

Some of the preceding steps have been demonstrated by the writer. In order to determine whether gaseous hydrogen is ever liberated under the foregoing conditions, a number of pieces of iron were immersed in dilute aqueous solutions of sodium chloride contained in glass tubes with a capillary top, and connected at the bottom with a small glass tube bent upward at right angles. Before being introduced into the glass tubes, the salt solution was boiled to remove the air, and afterward, before sealing off the tip of the capillary, a high vacuum was applied to the solution for some time. It was found that in all the tubes a greyish-green deposit slowly accumulated near the bottom, and at the end of several months a small quantity (0.1 to 0.2 cc.) of gas had formed in three of the tubes. This gas proved to be mostly hydrogen. In an investigation on the electrolytic decomposition of iron which is still in progress, it has been found that considerable quantities of cream-colored ferrous hydroxide may be produced under conditions analogous to the foregoing.

In addition to the corrosion of iron through the action of brine by the process just outlined, auto-electrolysis only occurs on account of the electrical potential differences which exist in commercial forms of iron due to the presence of segregated impurities. These differences, which are augmented by chlorides of the alkali metals, bring about a galvanic action that causes the iron to go into solution at certain points with the formation of oxide.

From what has been said, it should be clear that reinforced concrete which comes in contact with brine or sea-water will commence to deteriorate as soon as the brine comes in contact with the reinforcing rods; for, as both iron oxide and the hydrated oxide occupy a larger volume than the corresponding amount of iron, there will be developed an enormous expansive force, which is sufficient to crack the strongest concrete and force it away from the reinforcing rods. The more porous the concrete, the more rapidly will this disintegration set in. Indeed, the writer is familiar with cases of cinder concrete structures, in contact with brine which have shown signs of advance deterioration at the end of the year after their completion.

## WATER PROOFING PROCESSES NOT PERFECTED

Regarding the water-proofing of concrete, it should be pointed out that an impervious concrete is seldom obtained outside the laboratory. The average concrete is practically never waterproof. Although there are many substances on the market for rendering concrete waterproof, the majority of them are far from satisfactory. A number of such substances have been investigated by Brown<sup>1</sup>, who points out that all waterproofing materials will sooner or later hydrolyse, crack, or disintegrate. About a year ago the City of Philadelphia, upon the recommendation of the Franklin Institute, awarded the John Scott Legacy Medal to Max Ulrich Schoop, of Zürich, for his invention, the Schoop Metal Spraying Process. By means of this process various metals can be sprayed under high pressure upon any slightly roughened surface so as to form a smooth, adherent skin. After examination of the results produced by the Schoop process, the writer is of the opinion that by this means

Fig. 10—Badly shattered pillar due to corrosion of reinforcements. Figs. 11 to 15—Illustrate cases similar to those previously shown

concrete might easily be rendered impervious to water or brine.

#### PAINTING THE REINFORCING RODS

It has often been suggested that the deterioration of reinforced concrete through electrolysis might be prevented by the use of protective paints upon the metal that is to be imbedded in the concrete. A few years ago, the protective action of a large number of paints was very thoroughly studied by Gardner<sup>4</sup>, who points out that if the reinforcements are treated with suitable insulating and bonding paints before they are imbedded in the concrete, the causes which contribute to electrolysis will be guarded against and concrete structures will be rendered safe from deterioration through corrosion of the reinforcements. From the results of his investigations, Gardner concludes that the vehicle of such paints should contain: boiled or bodied oils or products which dry to a fairly saturated film, oils which dry by semi-polymerization rather than oxidation, and oils which dry to a flat rather than a highly gloss surface; while the pigment should contain a percentage of: pigments which are coarse and which, therefore, tend to form films having a rough surface, pigments which are inert and which do not act as conductors of electricity, and pigments which are either basic or of the chromate type. The metal should be sanded if possible.

#### EXAMPLES OF CONCRETE DETERIORATION

Since most concrete is more or less porous to moisture, and since iron undergoes gradual decomposition in the presence of salt water, with consequent expansion in

volume, it is to be expected that reinforced concrete that comes in contact with brine, sea-water, or salt and moisture will ultimately disintegrate. It is not surprising, therefore, to find reinforced concrete piers, sea-walls, and buildings in the neighborhood of the ocean in various stages of deterioration.

Today large reinforced concrete structures are used to house industries that employ large quantities of salt and brine, which are constantly spilled on the floors. In order to ascertain whether the concrete of such buildings had undergone any deterioration, the writer a few years ago examined a large number of them in many different cities throughout the United States; and in this paper he wishes to give a brief account of some of the cases of deterioration observed at that time. In practically all the buildings inspected, reinforced concrete floors which came into contact with brine had iron-stained cracks on the under side. These cracks, which nearly always ran parallel to the reinforcing rods, were usually very narrow, but they indicated, nevertheless, deterioration of the reinforcements, and would continue to grow as the disintegration of the iron progressed. Fig. 1, which is a photograph of a ceiling of a large reinforced building in Detroit, the floors of which are continually wet with brine, is a typical example of one of these iron-stained cracks in the early stages, and Fig. 2 shows a cracked horizontal beam supporting the floor of a reinforced concrete building in Chicago. In many instances, where the deterioration had been in progress for some time, the cracks were found to vary from  $\frac{1}{4}$  in. to  $\frac{1}{2}$  in. in width, and in some cases the deterioration had progressed so far that large pieces of

<sup>4</sup>Gardner. Journ. Franklin Institute, 179, 313 (1915).

concrete had fallen, or were about to fall, leaving badly corroded reinforcements exposed, as illustrated in Fig. 3 (photograph taken in Buffalo). An examination of a number of pieces of this fallen concrete showed that in every case a quantity of iron oxide adhered to the concrete where it had come in contact with the reinforcing rods (Fig. 4), and that it was sometimes as thick as  $\frac{1}{2}$  in. Where the concrete had broken away from the reinforcements, the latter were usually so badly corroded that it was possible to remove thick layers of oxide with the fingers. In a few cases the deterioration had progressed to such an extent that the reinforcements had been completely converted into oxide. Fig. 5 shows pieces of iron oxide,  $\frac{1}{2}$  in. to  $\frac{3}{16}$  in. thick, which were pulled away from corroded reinforcements or beams with the fingers.

A few details regarding particular cases of deterioration observed in some of the reinforced concrete structures examined may be of interest.

The ceiling of a machine-shop of a reinforced concrete plant in East St. Louis was found to be very badly damaged. This building, at the time of inspection, was about ten years old. The upper side of the ceiling was continually wet with brine, which continually leaked through to the under side and wetted it in a number of places. On this ceiling large brown iron-stains were numerous, and in at least twenty places pieces of concrete had fallen, leaving badly corroded net-iron reinforcements exposed. In one place, a piece of concrete 12 ft. long and varying from 2 in. to 18 in. in width had broken away. The reinforcements of this ceiling were imbedded at a depth of about  $\frac{3}{4}$  in. from the surface. Photographs of this ceiling are shown in Figs. 6, 7 and 8. Examples similar to these have been observed by the writer in Chicago, Kansas City, Detroit, and Buffalo.

At a plant in Kansas City that were found several very interesting cracked reinforced concrete pillars which supported a reinforced concrete platform at the top of an outside staircase. Large quantities of salt were used in the plant, and the platform was often wet with brine. The cracks on these pillars ran parallel to the longitudinal reinforcing rods. In some places the concrete had fallen away from the rods, which were badly corroded, and in other portions of the concrete were easily pulled away. Photographs of these pillars are shown in Figs. 9 and 10.

At another plant in this city there was a long outside platform, from which cars were loaded, covered by a reinforced concrete roof. At one end of this roof there was a pile of rock salt, which was partially protected from the weather by a wooden roof. Rock salt had been stored in this place for years. For a number of yards beyond where the salt was stored it had been spilled continually on the concrete roof, and owing to rains, perhaps a quarter of the roof was frequently wet with dilute brine. On the under side of the roof, directly below this place, there were many brown iron-stains, wet patches, salt deposits, and in one place the concrete had fallen, leaving the net-iron reinforcements exposed. These had deteriorated to such an extent that the outer portions crumbled on touching and some of the rods were easily pulled away. The area from which the concrete had fallen was at least one square foot. The individual rods of the exposed net-reinforcing, originally about  $\frac{1}{2}$

in. in diameter, had increased to about  $\frac{3}{4}$  in. in diameter, owing to the conversion of the iron into oxide. Some of these rods had disintegrated to such a degree that the sound iron core was less than  $\frac{1}{16}$  in. in diameter. Near where the concrete had fallen, it was evident that the expanding reinforcements were gradually forcing the concrete downward. At the far end of the ceiling, where salt had not been spilled above, there was no evidence of deterioration and the concrete was in an excellent condition.

At a third plant in Kansas City, a five-year old reinforced concrete basement ceiling was found to be in a very bad condition. This ceiling was reinforced with 3-in. twisted iron rods. The floor above was more or less wet all the time, and in places salt came in contact with the water, forming brine. There were many cracks on this ceiling, some of which were sufficiently wide to insert a lead-pencil. One such crack was 20 ft. to 30 ft. in length. In several places large pieces of concrete had fallen, leaving corroded reinforcements exposed. In one place a large piece of concrete which was almost dropping and which weighed about 25 lb. was easily pulled away from the reinforcements. The under side of this, as is usually the case, had a large portion of the corroded reinforcements adhering to it.

The writer examined a building in Kansas City which contained a large quantity of reinforced cinder concrete that came into contact with considerable amounts of brine. This concrete, which was thirty years old, was in a very damaged condition, and in many places very large pieces had fallen.

In one of the Chicago plants examined, a whole floor had collapsed about a year previously, owing to the weakening of the reinforcements by disintegration.

Similar cases to the foregoing have been found by the writer in a number of cities in different parts of the country. Excellent examples of deterioration of reinforced concrete found in Buffalo are shown in Figs. 11, 12, 13 and 14.

#### WINTER POURED CONCRETE SHOULD NOT BE SALTED

When concrete construction is carried out in winter, it is sometimes the practice to add salt to the concrete to prevent freezing, often as much as 20 per cent being added. The writer has examined a number of reinforced concrete structures where salt had been mixed with the concrete during construction. As is to be expected, where the concrete comes in contact with water or moisture, there are manifold evidences of deterioration; but, on the other hand, where the concrete has been kept dry no damage has been observed. An example of deterioration due to this cause is shown in Fig. 15.

Examination has been made of a number of reinforced concrete tanks used for storing both water and brine. In all of these tanks it was observed that the liquid slowly percolated through the concrete, that the inside surface of the tanks was soft, and that, although these tanks had only been in use for less than a year, the strength of the concrete was much less than the normal strength. These effects were much more marked in the tanks which were used for storing brine.

The following conclusions are drawn by the writer from his investigations of the action of salt, brine, and sea-water on reinforced concrete:

1. All concrete which is not waterproofed in some way is more or less porous to water and brine.

2. Brine readily softens the surface of concrete, and, therefore, more easily penetrates to the reinforcements, on which it exerts a disintegrating action that, owing to the attendant expansion, gradually weakens the concrete, causing it to crack and split, and in some cases to fall away from the reinforcements.

3. The more porous the concrete, the more rapid the disintegration of the reinforcements through the action of brine.

4. Reinforced concrete floors which come in contact with brine will gradually develop leaks. These will be followed by incrustations of discolored salt on the under side, where, later, iron-stained hair cracks will develop, running parallel to the reinforcements. As the deterioration progresses the cracks will widen, and, owing to the great expansive force of the accumulating iron oxide, the concrete will be gradually pushed from the corroded reinforcements and ultimately fall.

In view of the foregoing conclusions it is evident that reinforced concrete immersed in brine or sea-water is liable to subtle and persistent deterioration, due to electrolytic action between the salt and the reinforcements. Therefore, the permanence and durability of reinforced concrete ships is a matter of considerable doubt, unless the sea-water is prevented from coming in contact with the reinforcements. Such prevention may be effected by coating the reinforcements with the protective paint, such as has been described, or by applying to the outer surface of the concrete some material which will render it waterproof. Since most of the substances which have been used for this purpose give results which are far from satisfactory, the writer suggests that good results might be obtained by coating the concrete with a very thin layer of a suitable metal by means of the Schoop Metal-Spraying Process. Finally, concrete that is to be used in the construction of ships should undoubtedly be made from cement of fine pulverization, low in alumina and high in silica, free as possible from gypsum, absolutely free from lime, slow in setting and quick in hardening.

Swarthmore, Pa.

## War Department Authorizes Construction of New Plants

Authorization to proceed with the following building has been given to the Construction Division of the Army.

The construction of a phosphorus plant at or near Fairmont, West Virginia. The estimated cost is \$500,000 and the contract has been let to the American Phosphorus Company.

The construction of a tetryl plant at Senter, Michigan. The estimated cost is \$250,000. The foregoing amount is divided into the cost of the construction of the necessary buildings and equipment, included in which will be the boiler and power houses, facilities, packing houses, magazines, tramways and, in fact, everything to make a complete plant.

Additions and extensions to the Frankford, Penn., arsenal have been begun under the direction of the Construction Division. It is estimated that these will cost

\$1,000,000. The work consists of the extension of the loading room, annealing rooms, action press shop, barrack buildings, additional storehouses, stable, carpenter shop, a forging plant with equipment, a sea-wall along Frankfort Creek and other work to facilitate the production program at this point.

## Furloughs and Deferred Classification for Chemists

The Chemical Warfare Service has been duly authorized, by order of the Secretary of War, to make the necessary arrangements through the Adjutant General's Office to secure furlough, without pay or allowances, of such chemists as are necessary in such Government Bureaus as the Bureau of Standards, Bureau of Chemistry, Bureau of Mines, United States Patent Office, where such chemists are engaged in chemical work for the Government, or State Bureaus concerned, essential to the prosecution of the war. At the same time they are advised that the new Selective Service Regulations to be published shortly, will emphasize to the draft boards the fact that skilled employees of war industries should be placed in deferred classification. The induction into the military service of skilled men necessary to essential industries or occupations, to be subsequently furloughed back to their industries or occupations, involves an expense to the Government, and the men concerned lose time from their necessary work. The Bureaus concerned are authorized by the Selective Service Regulations to submit to the draft boards affidavits and written proof to maintain their contention that their employees should be placed in deferred classification and it is believed that they should be encouraged in securing deferred classification rather than securing the furlough of the men after they have been inducted into the military service. Communications relative to the matter should be addressed to Major Victor Lehner, C.W.S., 7th and B Streets, Washington, D. C.

## Carborundum Refractories

The article on this subject by Mr. C. S. Linbarger published in our daily issue for September 27 was originally presented at the meeting of the American Ceramic Society, New York City, September 26. Through an oversight we failed to give the customary credit to the Society, and due acknowledgement is made herewith.

## Imports of Rubber to January 1, 1919

The previous rate of permitted importations of crude rubber, effective up to Oct. 1, 1918, has been continued by the War Trade Board, in a new ruling (W. T. B. R. 248) for the final quarter of the year. Importations of crude rubber from overseas during the months of October, November and December, 1918, will therefore be limited to 25,000 tons, or at the rate of 100,000 tons a year. One-fourth of this amount will be licensed only from Central and South America. The remaining three-fourths may be licensed from any country. The amount so permitted to come forward will be allocated by the Bureau of Imports along the general lines of the previous allocations (Rulings 115 and 238).

## Development of the Magnesium Industry\*

BY LEONARD WALDO

IN THINKING over this subject the question arises whether there is, as yet, a development of the Magnesium industry on any such scale as we American engineers would call a development. I think of the time 35 years ago when in the Cowles works at Lockport, we had first harnessed Niagara at the overflow of the Canal Locks and had commenced with much fanciful hope the production of aluminium, which was, with its lightness going to decrease the weight of railroad carriers and metal structures by two thirds, and, because of its universal presence in the earth's crust was to displace the less abundant and heavier copper and iron, in many engineering enterprises.

Alas, the unthought of prevailed; the inertia of the world's customs, traditions and industrial practices made for a delay of years until aluminium should find its place and its comparative qualities should be widely known. Then the opening for its use occurred in a totally unexpected direction. It was found that the quality of steel could be improved by its use and thereafter a sufficient quantity of aluminium was produced to place its manufacture on a marketing basis, until now with the war demand, it is probable the annual production in our country of the Aluminum Co. of America amounts to 400,000,000 lb.

With this example of trade inertia before us, it is not surprising that magnesium would have to seek its natural applications before its manufacture could be placed on a basis at all commensurate with the more important metals. We find that in 1883 for instance, the European price of magnesium of 99.7 per cent purity was \$32.43 per lb. and that in 1902 with a world's output not far from 2500 lb. the price per lb. was \$2.82, approximately the price at present fixed by the United States government.

Magnesium has been known to metallurgists as a Cinderella sister to aluminium. It had such greater powers as a de-oxidizer in steel practice that the first attempts to use it commercially resulted fatally to the workmen. In action with the thermit process, it again showed uncontrollable vigor. In weight it is but 63½ per cent as heavy as aluminium and weighs 109 lb. per cubic foot. It exceeds in electric conductivity an equal weight of aluminium. It has a more beautiful color and is stronger than aluminium. Its specific heat is very high, ranging from 0.24922 between 20 and 100 deg. C. to 0.43516 at 625 deg. C., more than twice that of iron. Its oxide fuses at a temperature higher by 800 deg. C. than alumina. Peculiar and unexplained phenomena were noticed in the combustion of magnesium in the air. Woods showed that more heat was developed for equal amounts of oxygen taken up than in the case of any other known metal.

### COMBUSTION OF MAGNESIUM FOR LIGHT

Rogers as early as 1892 announced that the spectrum of burning magnesium more nearly resembled that of the sun than did any artificial illuminant; although the character of the spectrum, if it is due to ordinary in-

candescence, corresponds to a temperature of nearly 5000 deg. C.; while the radiant energy emitted is 75 per cent that of the total heat of combustion, and the light-giving power of magnesium per unit of energy expended is from 50 to 60 times that of gas. Later Nichols showed that incandescent magnesium emits light under conditions different than carbon and that it is more like the sun than that of any other source; that it is ten times as brilliant in the violet as the gas flame for equal luminous intensities, and one-half less in the red; also it surpasses that of the arc lamp in the yellow. Nichols assumes that here the law of radiation differs essentially from that of the ordinary incandescence. Can it be that we are encroaching on the ground of light production without the corresponding emission of heat? It is to be hoped that the activity of the U. S. Bureau of Standards along the lines of light emissivity as connected with the temperature of the highly refractory oxides, may not have to be curtailed on account of other war work researches, since it has a direct bearing on illumination for making photographic records of our war operations.

### COMBUSTION OF MAGNESIUM FOR RAPID THERMAL EXPANSION OF GASES

Closely connected with the luminescence of magnesium combinations is that of its relation to high military explosives. Its quickness of action in depriving nitrates, chlorates, manganates, sulphates and peroxides of constituent parts of oxygen with the accompanying extremely high temperatures instantly effective for expanding the volume of the released gases and other volatilized constituents gives magnesium a position among the best of explosive agents.

Here again we would be greatly benefited by a greater knowledge of the chemistry and physics of high temperatures; in fact, we know very little of the reactions taking place above, say, 1200 deg. C. in metallurgy. The few things we have discovered in these high-temperature regions are so helpful to war efficiency that it would be good if our researches were more extended in this difficult field. For example, the whole theory of the formation of the compound carbide of chromium, tungsten, and iron and their freeing at high temperatures to prevent the reversion of the reaction is the very basis of high-speed tool-steel production and hence the production of heavy ordnance on the lathe.

I cannot, for obvious reasons, at this time and place go into details as to present processes or results. I have mentioned these two recent applications of metallic magnesium to show that here we have an unexpected development, which sufficiently increases the demand for the metal to warrant the necessary capital, diversions of water-power and competent engineering to supply an amount large enough to tax present facilities and to encourage their rapid extension. We have, therefore, in the use of magnesium as an illuminant and as an explosive, the analogue to the use made of aluminium as a so-called deoxidizer in the case of steel. It is possible now to dismiss the market question for magnesium and consider some of its other uses.

### USES OF MAGNESIUM IN ALLOYS

For the last ten years or more, the cupro-magnesium alloys for scavenging brass have been a successful

\*A paper read at the Fourth National Exposition of Chemical Industries, New York, Sept. 27, 1918.

marketable product and thanks to our own brilliant and lamented Edwin Star Sperry, they obtained a place in copper alloy furnace work. The cost however limited their use. Probably with the present needs of greater economy in saving wastes in the casting shop and the higher prices obtained, the use of cupro-magnesium can now be put on a profitable basis as also the collateral use of metallic magnesium for controlling the pitch of copper in the reverberatory.

It was fortunate that in the establishment of the manufacture of magnesium by the Cunniff Brothers at Rumford Falls, Me., that a process for recovering the metal from a pure magnesia by-product was adopted. The early development of aluminium had been greatly hindered by the use of impure materials, and it is said by engineers to-day that the manufacture of aluminium sufficiently pure for modern metallurgy is entirely a question of making pure alumina. Modern alloys require a purity on a par with lake or electrolytic copper, Bertha zinc and Straits tin. The early aluminium alloys suffered greatly from such impurities as iron, silicon, and sodium. The present magnesium alloys fortunately are starting with an all but c.p. magnesium.

Of the flotilla of alloys using magnesium now streaming into the ocean of commerce, some have already been long enough in service to show what time, vibration, gaseous corrosion, alternate stresses, and water-vapor both on sea and land will do for them. Notable among these are "magnalium," of which there is a description in *Engineering* (London) for Jan. 5, 1906, and "duralumin" as described by Wilm in *Metallurgie* for 1911, pages 225-227.<sup>1</sup>

In these alloys, the specific gravity is kept near the 2.75 of pure aluminium. In other commercial alloys sold as aluminium, the specific gravity of the pure aluminium is increased by the addition of zinc or copper to about 3.2; but by the use of magnesium to replace such zinc or copper, the specific gravity would be somewhat reduced and we would have commercial aluminium alloys of 81 lb. replacing the same sizes of present aluminium of 100 lb. weight.

Some of the alloys of magnesium with aluminium are of extreme beauty; notably those which correspond to the eutectic, which is formed when the metals are combined in nearly equal proportions, the color of which is an ultra silvery whiteness and the texture, when the final meltings are made free from occluded gases, of microscopic fineness. This series is of great value for reflection of light in telescopes, in plane and curved mirrors. Because of its brittleness, an alloy of equal or nearly equal proportions lends itself to those powdering process where rotating hammers or stamp mills are used. Here, as in all processes for mixing powdered magnesium precautions are necessary to avoid explosions.

Years ago at Bridgeport we made certain small ingots for unknown but cash-paying customers, of rich-colored yellow aluminium bronze. Months later, we identified those same ingots in the police court after having been sold for genuine gold bricks. I am reminded of that occurrence as I think of the opportunity for the magnesium business now that this beautiful metal has come to stay, and is being made, to insure

purity and rapid production, from such costly sources as the magnesium-potassium alkali-chlorides, where there is but 7.3 per cent of metal available or of other chlorides where there may be 10 per cent! Think of the magnesian ophiolite in Canada with its 42.5 per cent bulk of magnesium, or of Salt Lake, Utah, with its 0.56 per cent of magnesium, or of Old Ocean himself with his  $\frac{1}{2}$  of 1 per cent at our feet. As for other sources, besides carnallite (natural or artificial), we have kieserite, magnesite, dolomite and in fact some 51 out of 768 minerals, and the bitters of the sea in collecting sea-salt. In ordinary sea water, a cube of 30 feet dimensions contains a 2240-lb. ton of magnesium.

Current production, with two plants of the American Magnesium Corporation at Niagara Falls, N. Y. and Rumford Falls, Maine, formed by the merging of the company of that name with the Rumford Metal Co., may be considered larger than that for the first half of 1918, which according to the United States Geological Survey was 116,938 pounds.

The time has not yet come for the prototype of Captain A. E. Hunt's classical paper on the "Manufacture of Aluminium by Electrolysis and the Plant at Niagara for its Extraction" published in the *Proceedings* of the Institution of Civil Engineers in 1896, but within a few years to come, with war conditions removed, it will be possible to reveal to the full the technique of production and the power and capacity in manifold directions of the most attractive of all metals—magnesium.

---

The President has approved the maximum prices on sulphuric and nitric acids, fixed at a meeting between the Price Fixing Committee and the manufacturers on September 26, 1918, these prices being effective from September 30, 1918, to December 30, 1918.

### Control of Tin Imports

B. M. Baruch, chairman of the War Industries Board, announces that under the recent decision of the War Industries Board to take control of the domestic pig tin situation by a license system the United States Steel Products Company only will be granted import licenses, this company to act under government direction and in the interest of consumers.

All users and dealers in pig tin will be licensed, and will secure their future requirements of pig tin from the United States Steel Products Co., which will make distribution under the direction of the War Industries Board.

The Inter-Allied Tin Executive, who will carry out the terms and agreements of the Inter-Allied Pig Tin Pool recently arranged in London, will control the buying price in each producing market. The War Industries Board will control the prices and terms under which the pig tin is to be sold to the domestic users and dealers.

Preliminary to the issuance of licenses to the users and dealers in pig tin an inventory of stocks on hand and contracts unfilled by the 2000 odd individuals and plants affected is being made by the Tin Section of the War Industries Board. If necessary, there will be a re-distribution of the stocks on hand to equalize them according to essential uses.

## Housing at Tyrone, New Mexico

An Account of the Systematic Efforts of the Phelps Dodge Corporation to Provide Wholesome Living Conditions and Harmonious Surroundings for Its Employees—Not An Experiment in Philanthropy, but a Wise Business Policy

By CHARLES F. WILLIS

Consulting Supervisor Department of Industrial Relations,  
Phelps Dodge Corporation

IT IS BELIEVED that when the engineers of the Phelps Dodge Corporation first investigated the property now known as their "Burro Mountain Branch," the attractions of climate and the environment of Tyrone must have entered into consideration, for today this place may be described by an adjective that seldom fits a mining or smelting community—it is a charming spot.

Were it not for the newness of the buildings, one could almost imagine that he was in a prosperous town in old Mexico. The buildings carry out the extreme Spanish type of architecture, with their plastered walls in various pale tints of blue, pink, gray and tan, the plaster laid unevenly as was done in the days when plasterers were not as skillful as at the present time, the roofs of vari-colored tile, everything Spanish to the last detail. One would imagine that the buildings were all of adobe until he watched a new building in the process of construction and saw the wooden frames, the wire lath on the outside and button board on the inside. The charm of the Spanish type is there, however, in the crooked corners of the window casings, the "hand hewn" timbers, aged with burnt umber, and, true to type, we further find that most of the buildings are occupied by Mexican laborers.

### GENERAL LAYOUT OF VILLAGE

It is indeed fortunate that this property was purchased by an organization with broad policies, as it would have been a pity to have put an ordinary camp in the site which Tyrone occupies. The long, broad valley of the Mangus River, eleven miles out of Silver City, formed the axis line for the center of the town, and from this valley at right angles, several smaller valleys branch, of sufficient size, however, to provide for the laying out of a street with houses on both sides. One picture a typical street of an industrial community as a row of box-like houses, all alike on the outside and with interior details identical. As is shown by an inspection of Table I, this has been avoided in the Tyrone project by the adoption of some twenty odd houses, the types so scattered that it is unusual to find two alike in the same neighborhood.

The town was primarily laid out in sections. The community center is of course the plaza, surrounded by a group of fine buildings. Radiating from this are numerous canyons, each assigned to a definite purpose. On the southwest is Pinal Street, the lower end of which is built up with what is known as Type G, H, K, and J apartments. These two- and three-room houses, shown in Figs. 4 and 5, are designed to be rented to Mexican laborers who wish homes at low rentals—from six to

twelve dollars monthly. The upper end of this street is surveyed in lots to be leased to Mexicans at a very nominal rental, where they may build their own homes. On the west side, leading directly out of the park, is Bellotal Avenue, bordered by similar houses for the Mexicans, as well as by a branch canyon from Bellotal Avenue, called Encinal Street. On the northwest side of the square is Fortuna Street, which leads up another canyon divided into lots which are leased to Americans with a \$1000 building restriction. On the southwest side is Coronado Street, subdivided for Americans into lots with no building restrictions. Leading from the plaza and winding up and over the hills to the mine is what is known as "the Hill," and along the well-graded roadway are fine residences for Americans. As seen in Fig. 6, there is no regularity as to their location or their setting, and they are of many different types.

### PHELPS DODGE POLICIES

Tyrone is distinctly a company-owned town; no land has been sold nor is it planned to sell any. There are advantages and disadvantages in living in a company-owned town, depending upon the policies of the company; fortunately for Tyrone the Phelps Dodge Corporation is particularly liberal. The store of the company (Fig. 3) is located in a prominent place on the plaza, but almost directly opposite is the fine building shown in Fig. 7 which has been leased at a very low figure for an independent store, in order to give their own store competition. This is the case in all lines of business, competitors being supplied with the necessary quarters to compete with Company enterprises. Every effort is being made to make it a town where the cost of living is low and to a great extent these efforts have been rewarded. The policy of the company is to have satisfied workmen who will stay with them year after year, who appreciate homes and who know that the company cares for their well being as well as for the profits from their properties. It is not by any means an experiment in philanthropy, but rather a policy of far-seeing men who recognize that the development and building of the community simultaneously with their business will bring greater profits, indirectly, but surely. They believe that it will pay dividends in content and in the reduction of labor turnover.

### THE PLAZA

The plaza is surrounded by a group of fine business buildings, harmonious in type of architecture, but all different in detail. On the east side is the company office building (Fig. 8) containing the offices of the officials, the townsie department, and the engineering,

FIG. 12.—PINAL ST.: HOW MEXICANS LIVE WHEN LEFT  
TO THEMSELVES

bookkeeping, and auditing departments. On the northeast corner is the independent store, a confectionery, a refreshment parlor, a barber shop, a doctor, a dentist, a lawyer and a photographer. On the northwest side will be the employees' club house, yet to be erected. Beside the club house is a large school (Fig. 9) and in spite of the fact that the town has only four thousand people, it is reputed to be the best school house in the state of New Mexico. That Tyrone is being selected by workers as a place to bring up their families is evidenced by the attendance at the school. Although it was designed to be large enough for some years to come, the six hundred students attending last year made it necessary to erect an addition. The building was built by the company and leased to Grant County at a very nominal rental.

On the west side of the plaza is the department store of the Phelps Dodge Mercantile Co. (Fig. 3), and while large centers of population may boast of stores of greater floor space, they cannot boast of a more beautiful building. On the southwest corner is the railroad station and post office building, both of which are fitted to carry out the same general scheme, while on the southeast is to be the hotel, work on which has been stopped for the period of the war. Situated but a short distance away from the plaza and yet readily accessible to it is a garage, a large restaurant and a moving picture theater, and the company has even taken upon itself to build the "hoosegow" or jail in a pretty little park (Fig. 11). A central heating plant provides for all of the buildings surrounding the plaza and for carrying out the Spanish type of architecture; where steam radiators would seem out of place, the radiators are carefully concealed in the walls, under the seats in the station, and by various ingenious devices. The plaza itself is a beautiful spot with large grass areas, and will soon be equipped with the necessary band stand. The absence of "keep off the grass" signs is noticeable, the management believing that grass plots are made to use rather than to see.

#### DETAILS OF THE HOUSES FOR LABORERS

In the type of houses designed for the Mexican labor there are electric lights, sewer connections, water and gas. The type G house has six two-room apartments, which rent for \$6 per month; type H is a double two-apartment house renting for \$8 per month; type K has two three-room apartments which rent for \$9 per month, while type J is a single three-room house renting for \$12 per month. The other types vary from two to six rooms, renting at about \$5 per room. Types G, H, J, and K houses have flush toilets on the outside as a separate structure, although in the latest type G they are inside. Each room has electric plugs for iron, toasters, percolators and other electric devices. The earlier houses have cement floors in both the front and rear rooms, but the latest have wooden floors in the front and cement in the back.

The housing project of Tyrone was started in the summer of 1915 and besides the central plaza and its group of large buildings, 229 apartments have been built to date, and more are in the process of construction. One of the results has been the education of the Mexican laborer to better methods of living. At first it was found that the Mexicans preferred to rent a piece of land at fifty cents per month and build their own

shacks like those of Fig. 12 rather than rent a company house. However, the houses are now taken up by a waiting list and cannot be built fast enough. Moreover, there is a growing demand from the Mexicans for larger and better houses having three or four rooms and bath.

#### GENERAL RESULTS

Tyrone is a spotless town. The sanitary squad cleans the streets, empties garbage and does various other duties to keep the town clean. No charge is made the tenants for this service. Electricity is sold for seven cents per kw.-hour with a minimum of 50 cents per month. Water is furnished for 50 cents per thousand gallons with a minimum of three thousand gallons per month, with an additional cost of 35 cents per thousand gallons for a garden. The management is now planning

FIG. 13.—THE T. S. PARKER HOSPITAL

the diversion of some of the mine water, however, to take care of the latter.

## The Rôle of Colloids in Chemical Processes\*

IN a recent conversation with a chemist well known throughout the country for his contributions to industrial research, he remarked: "There seem to be fashions and styles in the problems that are brought to us. Sometimes these are mostly of a metallurgical nature, at other times they are inorganic or again organic, while of late, the bulk of the problems that have come before us are in the realm of applied colloid chemistry."

Some of us, too, studied the subject when the memory of Thomas Graham was under a cloud of neglect, or in Germany before Wilhelm Ostwald washed the cloud away to find a field of distinction for his son Wolfgang. Then, as we grow older, we read and forget, and need to have our memory jogged a little to refresh our consciousness of certain important things. With this purpose in view and to bring to the notice of our readers two forthcoming chemical books of importance, we shall extract a few notes on the subject in general and then proceed to add memoranda on applied colloid chemistry from the sources mentioned.

The colloid field has to do with the properties of particles of the approximate diameter of from  $0.1\mu$  ( $0.0001$  millimeter) to the point where crystalloidal solutions begin, which is less than  $10\mu$ . ( $1\mu = 0.001\mu$ ). The smallest particles that can be seen with the ultramicroscope are of about  $5\mu$  diameter. The theoretical H molecule is about  $0.1\mu$ . Then if a human red blood corpuscle were  $25$  ft. in diameter by way of comparison,  $5\mu$  would be quarter the size of a man's finger nail and the H molecule would be hardly more than a speck. Now since it is the surface of these particles which presents their most distinguishing characteristics, let us observe that while one cubic centimeter presents a surface area of  $0.93$  square inches, if it were divided into  $0.1\mu$  cubes we should have  $1,000,000,000,000,000,000$  cubes presenting a surface area of about  $21\frac{1}{2}$  square feet. And if we were to divide it into cubes of  $0.1\mu$ , we should have a million million million cubes presenting a surface of nearly fifteen acres.

We are constantly considering the wandering of particles but sometimes an example is worth while, to show their ways. Here, for instance, is one that is graphic: If we give a man a few grains of lithium chloride and shortly afterward wipe his forehead with a clean platinum wire, the lithium will show in the spectroscope. With the Faraday-Tyndell effect, however, in a solution of  $0.1\mu$  colloidal gold, less than one ten-millionth of a milligram may be detected with the naked eye.

As colloidal particles coalesce, energy seems to be developed. This manifests itself (or "orients" itself as is said in translations, from the German "*orientiert sich*") as lightning in the case of clouds or as heat in the case of metals. Here is a grand field for study and the most delectable playground for speculation.

Protection in the colloidal sense produces a surface skin or pellicle which surrounds each particle and prevents it from coalescing with others. It exercises a

two-fold function: In crystalloidal solutions it provides that reactions take place in detail as it were rather than *en masse*, or, to use a foot-ball simile, it provides for contact in open formation rather than by a flying wedge. After the aggregation of crystalloidal particles into those of colloid dimensions it surrounds these and prevents their union.

Let us note at this point that the radius of molecular attraction is about  $50\mu$  or just within the colloidal field.

*Adsorption* is a phenomenon that goes farther than some of us are disposed to think. For instance, a solution of  $K_2SO_4$  filtered through sand gives a dilute solution of  $H_2SO_4$ . Dissociation has taken place. This fractional dissociation is more observable in electrolytes, for certain salts dissolved in a gel dissociate, and some of their ions diffuse faster than others so that complete separation may take place. Very pretty experiments may be performed in this connection by the use of different indicators in a test tube. Ions of crystalloidal electrolytes receive an electric charge as they are adsorbed by colloidal particles and this results in stabilizing the dispersion. As the iso-electric point is reached, where the charge equals zero, coagulation occurs.

The application of colloid chemistry is so wide that we can give only selected memoranda on the subject.

*Clay and ceramics.* The first historical note we get is in the fifth chapter of Exodus, where it is recorded that the Egyptian taskmasters compelled the children of Israel to make bricks without straw. The use of the straw was not, as is generally supposed, on account of the fibres which served as binders. It was a colloidal substance contained in the straw which caused the particles to deflocculate. Recent patents have been taken out for "Egyptianizing" clay by adding to it tannin, extract of straw, humus and the like. Protective colloids such as glue etc. deflocculate or "free out" clay and make it spread or cover, as in paper coating and kalsomining. The working properties of clay depend largely upon the size of the particles and their state of aggregation. This explains the uselessness of chemical analyses which give only percentage content, if the clay is to be used for certain purposes. Articles moulded of clay and then burned lose their hydrosol condition and become hardened into pottery.

In agriculture it is colloid chemistry that is in large measure the chemistry of practice. The quality of soils has a great deal to do with organic colloids which are found in it, as well as with the size of the soil particles. We have not space even to touch upon this great field.

In electroplating the addition of protective colloids tends to the production of non-crystalline deposits.

*Metallurgy.* Since coarsely crystalline metals are brittle, tending to split along the line of crystal cleavage, various physical or chemical means are employed to obtain a fine hard-grained structure. Among the physical methods are chilling and rolling, while chemical methods involve the removal of undesirable constituents (as in the conversion of pig iron to steel) or the addition of desirable constituents (as in case-hardening or the manufacture of alloy steels). For instance, it is shown that the predominant effect of vanadium in steel is to decrease the size of the ferrite grains and to make the material harder; it renders the ordinary structure due to pearlite fine and homogeneous. While the question is one of great complexity, many facts at present

\*EDITOR'S NOTE. We have been permitted to look over the proof-sheets of Mr. Jerome Alexander's forthcoming book on "Colloid Chemistry" as well as his contribution of "The Practical Application of Colloid Chemical Principles" to the new edition of Rogers' "Industrial Chemistry," and we believe a few notes from them to be timely.

available seem to indicate that one of the causes favoring the fine-grained structure in such instances is the inhibition of crystallization by substances colloiddally dissolved in the molten mass. Thus, part of the carbon in iron and steel is graphitic, and as graphite is slightly soluble in iron, under proper conditions some of it will assume a colloidal form and act as a protector.

An interesting research note follows: Moissan said that the addition of a little platinum to metallic mercury caused the latter to emulsify in water. Upon making the experiment, according to Moissan, Mr. Jerome Alexander noticed that the supernatant liquid remained turbid. On standing, examination of the fluid in his ultra-microscope revealed the presence of colloidal metallic particles in active motion.

In dyeing, colloid chemistry throws light upon points which were heretofore obscure. For instance, it is possible to obtain more level colors in old dye liquors than in fresh ones, and the explanation proposed is that colloiddally dissolved substances are responsible for the phenomenon in that they exercise a restraining action upon the adsorption of color. They slow down the process. The level dyeing facilitated by the addition of Glauber's salt may be due to its action as an electrolyte producing a partial coagulation of the dye-stuff so that its particles, thereby made larger, are adsorbed more slowly and evenly.

**Soap.** The colloidal nature of soap solutions is indicated by their turbidity and their gelatinization. The detergent action of soap is consequent upon its deflocculating effect as was shown in the Cantor Lecture of H. Jackson (*Journal Soc. Arts*, 55, 1101, et seq.) who examined microscopically the supernatant fluid from washing a dirty cloth and found in it countless particles in a state of oscillatory motion ("pedesis"). When an individual fibre was bathed in soap solution, the dirt particles gradually loosened and began to oscillate, while upon substituting salt solution for the soap, the particles flocculated and the motion ceased. Mr. Alexander observes that an ultra-microscopic examination of the detergent effect produced by soap should prove of interest. The subject has long needed explanation and no one is better qualified to blaze the trail. The answer certainly seems to lie over in this field.

In regard to transparent soaps, there is a memorandum of an original experiment by the author which has a bearing upon metallurgy. According to W. D. Richardson, a transparent soap is a supercooled or supersaturated solution, having crystalline tendencies and exhibiting colloidal properties. Bearing in mind that the salts of the higher fatty acids dissolve in water as colloids and in alcohol as crystalloids, and also that alcohol or equivalent solvents such as glycerol, sugar etc. are used in transparent soap, it seems probable that the crystals which frequently form in it are due to the slow separation of such part of the soap as is in crystalloid solution. The crystalloid phase of soap is apparently governed by the same factors as those which Tamman pointed out as governing the crystallization of supercooled solutions: first, the specific power of crystallization; second, the speed of crystallization; and third, the viscosity. It seemed to Mr. Alexander, therefore, that an important factor in determining the transparency of transparent soap would be the speed of cooling, and he made some experiments

along this line. A piece of commercial transparent soap was melted and cast into two cups, one of which was quickly chilled in ice, while the other was allowed to cool slowly by immersion in hot water. The quickly cooled piece was transparent while the other was practically opaque and showed on ultra-microscopic examination much larger ultra-microns than the transparent piece. After standing three or four months, the quickly cooled soap was still transparent to the naked eye, whereas large opaque spots could be seen in the slowly cooled piece. In the ultra-microscope the former appeared as before, whereas the latter showed large and perfectly resolvable crystals in a clear matrix.

These experiments give us an inkling as to what occurs during the "heat treatment" and tempering of metals, and it is to be hoped that some technique may be devised that will give us even a clearer insight than does etching into the changes that occur in metals in heat treatment, use, age, and even "disease" (tin for example).

**Milk.** This product contains salts and sugar in crystalloid solution, casein and lactalbumen in colloidal dispersion and milk fat in suspension. Upon reaching the stomach the casein of cow's milk coagulates into great hunks; that of mother's milk into fine flakes; and that of mare's milk remains almost fluid. That cow's milk is indigestible by many persons and may not be taken with impunity by infants is well known. The addition of protective colloids to cow's milk stabilizes it and makes it act more like mother's milk when treated with acid and rennin. If sufficient protective colloid be added the coagulate may be kept in a very fine state of subdivision. Gelatin and gum arabic are used for this purpose. Sodium citrate also acts as a protective colloid.

Ice cream, as those who make it know, if made without eggs, gelatin or some similar colloidal ingredient, is gritty, grainy or sandy, or it will soon become so upon standing, whereas ice cream made with small quantities of protective colloids has the rich, mellow, velvety texture so much desired. The colloid acts as an inhibitor of crystallization and as a preserver of texture. It is also very beneficial from a digestive point of view. Nevertheless, some official food chemists of the type that use publicity bureaus for their laboratories and newspaper columns for their literature have been known to declare the expensive and desirable gelatin to be nothing but "filler," and have cautioned the public against it.

**Tanning.** The skins of animals constitute an organized colloid jelly formed of bundles of fine fibrils, about 1 $\mu$  in diameter, bound together by a cementing material of similar chemical composition which is largely removed by liming and other treatment which precedes the tanning proper. When the swollen hide is placed in the acid tanning solution, the tannin is powerfully adsorbed by the fibre and combines with it to form leather. The positively charged hide and the negatively charged tannin naturally coagulate each other. If the tar liquor is alkaline, both the tannin and hide become negatively charged and no tanning occurs. Gelatin, when neutral and free from electrolytes, does not precipitate pure tannin, but in an acid solution it takes a positive charge and is tanned. The tanning process may be aided electrically by giving the

hide a suitable potential, positive in the case of tannin and negative in the case of chromium compounds.

**Rubber.** This product is made by coagulating the milky juice or latex of various plants. Rubber latices are emulsions stabilized by protective colloids (proteins or peptones) and the nature of the coagulant depends upon the nature of the protector. Vulcanization consists of the combination of sulphur with rubber. At first the sulphur is adsorbed; then by heating, part of it enters into a close combination, probably into a true chemical combination.

**Photography.** The photographic plate owes its sensitiveness to an emulsion of colloidal silver halides stabilized by a protective colloid (gelatin, albumen or collodion). The degree of dispersion is controlled by the condition of precipitation of the silver salt and the subsequent treatment of the emulsion. The latent image formed upon the exposure of the plate to light is probably an adsorption compound between colloidal silver and silver halides. This is an interesting definition of silver sub-halides and gives us a chance to think of bromine as mono-valent in this connection which is comforting to old-fashioned chemists who are likely to grow restive under the consideration of polyvalent halogens. It seems, under such conditions, as though the halogens had become addicted to evil practices.

**Cement, Mortar and Plaster.** When freshly mixed, mortar and cement contain colloidal sols or gels which gradually coagulate and set or bind the crystalline element of the plaster into a coherent whole. The setting of plaster of Paris has for many years been slowed down by colloidal retarders. Observations were made by preparing microscopic slides with equal parts of plaster of Paris and water to which had been added varying proportions of gelatin with the following results:

| Per Cent Gelatin | Time to Set in Minutes | Microscopic Appearance of Slide                                                                                                 |
|------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| 0.00             | 40                     | Characteristic interlacing crystals of calcium sulphate.                                                                        |
| 0.01             | 50                     | No true crystals except in a few spots where some colloid-free solution had diffused out. Elsewhere aborted spherulic crystals. |

In chemical analysis the presence of colloids may lead to grave errors, so that the chemist should destroy them by ignition or overcome their effects by coagulation. Reversible colloids, often referred to as "organic matter," may prevent the formation of precipitates, just as tartaric acid or tartrates prevent the precipitation of alumina, chromic oxide or ferric oxide. They may also prevent the satisfactory filtration of the precipitate formed or they may render precipitates difficult to wash and purify. As an example, three solutions of lead acetate were taken. To the first was added HCl which yielded a heavy, coagulated precipitate. To the second was added NaCl (a less highly ionized precipitant) which yielded a colloidal precipitate of lead chloride. To the third was added first a little glue solution and then sodium chloride; in this no visible precipitate was formed.

**Foods.** Here is a sentence that in these days of domestic economy and Kitchen Kemistry should be learned by heart and repeated often: It is a serious

error to judge foods upon the basis of a bald chemical or calorific analysis; fat, protein, carbohydrate and calories are not alone the criteria of food values; the physical condition of food largely governs its usefulness to the organism. For instance, light bread is more wholesome than heavy bread because the former presents an enormous surface to the digestive juices. In biblical times, unleavened bread was eaten only in time of stress. Again, the meats of young animals differ from those of old ones in that the latter are formed of tissues partially dehydrated by age. Notwithstanding all our talk, we have not yet reached a proper appreciation of the great art of cooking.

#### BODY AND PLANT COLLOIDS

**Physiology and Pathology.** The changes which occur in almost all physiological processes are produced at comparatively low temperatures and in the presence of very dilute reagents. The living organism disintegrates proteins, oxidizes carbohydrates and with the same apparent ease synthesizes substances of great complexity. The body and plant colloids (biocolloids) consist of carbohydrates (starch, cellulose, glycogen), proteins (plant and animal albumens) and lipoids (lecithins, cholesterolin, fats and oils). Each tissue has a normal turgor or state of swelling which is greatly influenced by acids, alkalies and salts. The swelling and shrinking of tissues, together with their selective adsorption and the differential diffusion of solutions through them, account for or accompany many physiological phenomena, both normal and pathological.

Thus, fibrin and gelatin swell much more in very dilute acid than in distilled water, but the swelling is depressed by salts. Fibrin is so sensitive that it swells in the presence of traces of acid quite undetectable by ordinary indicators such as litmus; in fact, fibrin itself is an extremely sensitive indicator, and can by its swelling actually distinguish distilled water from the still purer conductivity water.

Local accumulation of acid in the organism may cause swelling (edema); for example insect stings, which may be imitated by stinging gelatin with a needle dipped in acid. If acid accumulates in an organ within a rigid capsule (eyes or kidneys) the swelling tends to establish a vicious circle (glaucoma, nephritis) by compressing the blood vessels and cutting down the alkaline blood stream, which is unable to wash out the acids (mainly CO<sub>2</sub>) formed by living protoplasm.

If the oxidation processes of the body are normal, the hydrogen in foods is oxidized mainly to water and the carbon mainly to carbonic acid, a gaseous acid which is exhaled without demanding protein or fixed alkali of the organism for its elimination. In the case of pathological oxidation, however, other acids are formed and a condition called "acidosis" may arise. This is in reality a diminished alkalinity, recognizable by the fact that an abnormally large quantity of bicarbonate of soda is needed to render the urine alkaline. These acids may cause not only disturbances of the body colloids, but disease and even death. In fact, throughout life there is a gradual syneresis of the biocolloids, accompanied by visible shrinking and loss of water as is indicated by the comparison of the chubby hand of a child with that of an old man. In plants an analogous process occurs in lignification.

## Potash in Nebraska

By J. M. LLITERAS

IN 1912, when two students from the University of Nebraska filed claims on Jesse Lake with the purpose in view of extracting potash salts, no one thought they were starting an industry which a few years later was to be in the forefront in the State of Nebraska, and the industry which the farmers of the United States were to depend upon for their supply of potash fertilizer. These students, Show and Modesitt, tested various lakes in the "Sand Hills" of Western Nebraska and arrived at the conclusion that Jesse Lake would be the most profitable to them. The decision was a wise one, for there has not yet been found another lake equal to it. The Potash Products Co., and its successor, the Potash Reduction Co., has been drawing on Jesse Lake steadily for about five years, and it shows few if any signs of exhaustion.

There were many untouched lakes in this region, however, and today the present field from which the

shows conclusively that it is but a matter of time until the lake will fail to "come back." This will happen when the supply of salts to this particular lake has been exhausted. The reader may ask why it is that Jesse Lake, which was tapped first and has been drawn upon heaviest, has not given out. The answer is that the supply which is feeding this particular lake must be enormous, although it is not inexhaustible.

The loading stations for the Nebraska potash industry are at Antioch, Hoffland and Lakeside, all situated on the main line of the Chicago, Burlington and Quincy Railroad, near the division point, Alliance. Since the small lakes are scattered over a large area, it is necessary to pipe the brine to a central evaporating station. Most of the brine used today by the various companies is pumped from wells, the depth of which varies from 12 to 30 ft., depending entirely upon the nature of the lake in which they are placed. These wells consist of pipe,  $\frac{3}{4}$  to 2 in. in diameter, to the end of which is attached a well-point 18 in. to 6 ft. long. This point is imbedded in gravel, poured into the well

at the time it is bored and before the casing is withdrawn. The wells are spaced from 10 to 20 ft. apart, this distance again being governed by local conditions in that particular lake. The wells connect to a sub-header, while the various sub-headers in the system join the main header which is also the pump suction. At present very little is being done toward primary concentration of the brine at the place of pumping, so the brine as taken out of the lake is pumped to the evaporating plant through 4- or 6-in. pipe lines. Six-inch wood pipe is now being used exclusively on account of the scarcity and prohibitive cost of wrought iron pipe. In some instances

the wells in lakes have been pumped several weeks after the bed of the lake was dry. At other times fresh water was pumped in to cover the surface for two reasons: first, to keep the wells sealed so as to prevent air leakage into the main pipe system; and second, to allow this clear water to percolate through the sand bed, collecting in its travel any crystals of soluble salts with which it may come in contact before reaching the well-point.

Evaporation practice used in the Nebraska potash industry is nothing new, most of the companies using Swenson or Devine Evaporators. The Swenson system of evaporation may be readily understood by following the accompanying diagram, Fig. 1.

The potash-bearing water as it comes from the reservoir first enters the condenser where it liquefies the vapors from the third effect, producing in the latter a vacuum, the amount of which is governed largely by the

FIG. 1.—SWENSON SYSTEM OF EVAPORATION

various companies are pumping extends over an area of about 330 square miles. Potash has also been found in other lakes outside of this field; possibly the brine waters are scattered over a total area of about 600 square miles.

It has been definitely proved by the continuous pumping of certain lakes that the potash supply of Western Nebraska is not inexhaustible.<sup>1</sup> In fact, the water in the majority of the lakes lowers in density after being pumped for a certain length of time, there being a specific instance where a lake first delivered brine with a density of 10 deg. Bé., while after five months' pumping the density of the brine coming from the same wells was only 2 deg. Bé. Another peculiarity about these lakes is that if they are allowed to "rest" for a certain length of time, the density will increase and in rare instances assume the original specific gravity, only to decrease again after a second pumping. This

<sup>1</sup>See communication from W. A. Norris on this subject in *Metalurgical & Chemical Engineering*, Mar. 15, 1918.

temperature of the boiling brine contained in that cell. During its travel through the condenser the dilute solution naturally becomes hot, and the necessary fraction is taken through the pipe line marked "To second effect." The balance and greater portion of the water is returned to the reservoir through a spray system. The purpose of spraying this water is first to take advantage of the evaporation that will take place when the hot brine is sprayed into the cooler atmosphere, and, second, to keep the temperature of the liquid in the reservoir as low as possible. Brine enters the second effect at about the same density that it comes from the lake; there it is boiled under a vacuum of from 1 to 10 in. and a temperature of from 180 to 200 deg. F. by the heat given up by the vapors formed in the first effect. From the second effect the brine goes to the third effect where it is boiled under a vacuum of 15 to 24 in. and a temperature of from 130 to 150 deg. F. by the heat given up by the vapors formed in the second effect. Finally, from the third effect the concentrated liquor is pumped to the first effect, where it is boiler under a pressure of 4 to 12 pounds and at a temperature of 220 to 240 deg. F. by live steam from the boiler house. The process is a continuous one and is so regulated that the density of the brine in the first effect is raised to 20 deg. Bé. when the contents are pumped into the "concentrator" for further evaporation.

Each cell of the evaporator consists of a steel shell inside of which is a "basket" composed of many 2-in. tubes, the brine being around the basket and the steam inside it. In no case do the brine and the steam come in actual contact with each other. The concentrator, which is not shown in Fig. 1, is similar to a cell of the triple effect evaporator except that it is provided with a circulating pump to keep the brine agitated at all times. This is necessary in order to prevent any separated salts from settling to the bottom, which would invariably happen if the liquid were not kept in constant motion. Live steam is used for heating the solution in the concentrator. The density of the brine is here carried to between 30 and 40 deg. Bé., varying inversely with the amount of soda contained.

The efficiency of the above method of evaporation is constantly being improved by such expedients as placing a heater between the second and third effects, by using the exhaust steam from the concentrator for further boiling and by several other small improvements that will increase the density of the brine in its travel through the system.

Drying the salts has been a hard problem in this region, much money having been spent on various types of dryers while only one has proved at all satisfactory. We are now expectantly awaiting results obtained in a drier under construction by the Western Potash Works at Antioch, which is entirely different from anything ever tried before. The successful dryer in universal use consists of a cylindrical steel shell 30 to 45 ft. long, and 4 to 6 ft. in diameter. The saturated brine as delivered from the concentrator is sprayed into the cylinder at the upper end, and travels toward the fire end. The precipitated salts are thus subjected to the highest heat just before the brine is discharged from the dryer. The shell is provided with inner baffles and rollers to keep the dried salts from adhering to it.

This type of dryer will deliver salts with a moisture content as low as 0.5 per cent, although the most economical point has been found to be around 3 per cent.

The cool end of the dryer is connected to a dust chamber through which the dust and gases pass. Baffles catch the entrained dust quite successfully, and tests of the gases at the top of the stack show very little if any potash when the dryer is running under normal conditions.

Nebraska is now producing about 450 tons of salts daily, with an average potash content of 25 per cent. This production is expected to be further increased in the near future when the latest plant to begin operations comes into its own, and when two others which are now under construction begin operations.

Our potash industry has had its opportunity due to lack of German products. It developed during war times and naturally had to pay war prices for all materials. It had to educate its own labor and make living conditions in the Sand Hills such that it would be possible for families to settle there. It had an uphill fight all the way to prove that it was an essential industry and to get preference on all necessary materials.

A great question in the minds of many people today is whether Nebraska potash can compete with the German product after the war? However, this is not the question that is bothering the people financially interested in the industry. They are more interested in the excess profits section of the revenue bill now in Congress. If the bill does not allow the potash plants to write off their investments in the plants before heavy taxes shall accrue, it will greatly retard the industry; while if they are allowed the amortization of the plants first it will mean its salvation, and would greatly stimulate and promote the somewhat hampered production. Favorable action now would greatly help this new-born American industry to make the United States self-supporting after the war and make us independent of German potash.

Antioch, Nebraska.

### Importation of Copper Ore

The ruling of the War Trade Board (No. 211) affecting the importation of copper ore has been so far modified by a new ruling (W. T. B. R. 249) as to permit the importation of copper concentrates containing 50 per cent or over of copper from non-enemy countries, instead of 60 per cent or over as in the former ruling. The previous restriction prohibiting the importation of ore, except from Cuba, Canada or Mexico, and of copper concentrates containing less than 50 per cent of copper, except from the above countries, remains in force. There is no restriction upon the importation from any non-enemy country of copper matte, blister copper, or copper concentrates containing 50 per cent or more of copper.

### Synthetic Phenol

Attention is called to an error which occurred in the make-up of Mr. Peterkin's article on this subject in our issue for September 1. Titles of Charts I and II were inadvertently reversed.

# Aluminium and Its Light Alloys—V

**Duralumin Is the Most Remarkable Light Alloy of Aluminium, Resisting Corrosion and Possessing Important Physical Properties—Four Types of Deterioration of Aluminium Alloys**

By PAUL D. MERICA

## DURALUMIN<sup>1</sup>

THE most remarkable light alloy of aluminium is undoubtedly duralumin, the behavior and properties of which were discovered by Wilm (474) during his investigation during the years from 1903 to 1911. The remarkable feature about it is that, alone among light aluminium alloys, its mechanical properties may be vastly improved by heat treatment.

The composition of this alloy varies somewhat; on the continent the following range of compositions is used:

|                 | Per Cent |
|-----------------|----------|
| Copper .....    | 3.5—5.5  |
| Magnesium ..... | 0.5      |
| Manganese ..... | 0.5—0.8  |
| Aluminium ..... | balance  |

It is thus an alloy which can readily be rolled or forged; indeed it is always used in this condition, since the development of its highest physical properties involves the application of mechanical work to it.

The electrical resistivity of annealed duralumin is 3.43 microhm-cm.; in the heat-treated condition, however, in which it is always used, the resistivity is much higher, being 4.73 microhm-cm. In this condition it has approximately 35 per cent of the volume-conductivity of copper.

The density of duralumin varies from 2.75 to 2.84; its melting point is about 650 deg. C.

When this alloy is heated for a few minutes at temperatures from 400 to 520 deg. C. and quenched in water the hardness is very little increased over that which would be obtained by slowly cooling the same alloy. But upon aging the quenched alloy for several days at ordinary temperature both the hardness and the ductility are increased from 15 to 50 per cent, depending on the composition of the alloy and the quenching temperature. Thus an alloy showed the following changes of properties:

|  | After rolling,<br>before<br>hardening. | After hardening,<br>quenching<br>and aging. |
|--|----------------------------------------|---------------------------------------------|
|--|----------------------------------------|---------------------------------------------|

|                                       |        |        |
|---------------------------------------|--------|--------|
| Tensile strength, lb. per sq.in. .... | 37,000 | 58,000 |
| Elongation, per cent ....             | 17     | 23     |

The change of hardness during aging is shown in Fig. 22.

After hardening this alloy by quenching and aging, it may be still further hardened by cold work, at the cost, of course, of ductility. The curves, Fig. 23, show the increase of tensile strength and decrease of ductility that occur when both annealed and hardened duralumin are cold-worked.

The hardness produced by hardening is of course

lost upon annealing at rather low temperatures. The curves of Fig. 24 show the effect of annealing at different temperatures followed by air-cooling, upon the hardness and ductility of a hardened duralumin. It is noticed that duralumin hardens slightly even when cooled in air.

Duralumin loses its hardness at higher temperatures. Fig. 25 shows the effect of higher temperatures upon the hardness of this alloy.

Table XIX gives the results of a number of tests of commercial duralumin from the Dürer Metallwerke A. G.

TABLE XIX—EFFECT OF 14 MONTHS' IMMERSION OF DURALUMIN IN DIFFERENT SOLUTIONS. COHN (471, 473)

|                                | HgCl <sub>2</sub> 10 g             | 0.00                   | Material attacked but not brittle. No action.                   |

<sup>1</sup>Most of the data in the paragraphs on duralumin have been taken from articles by Cohn (471-473, 476).

Duralumin<sup>1</sup> when heat treated and cold worked to give about 6 per cent elongation in 2 in. corresponding to a yield point above 35,000 lb. per sq.in., will withstand unlimited alternations of stress between 0 and 20,000 lb. per sq.in. tension.

**Corrosion.** Duralumin in the hardened condition is remarkably resistant to corrosion, considering that it contains much copper which is recognized to be usually a harmful constituent of an aluminium alloy from the standpoint of corrosion. This fact is particularly important in view of the use of the alloy for construction

where it will be subject to weathering and corrosion.

The Dürer Metallwerke A. G. have made extensive investigation of this feature. Sheets 2.35 mm. thick were immersed for 14 months in several solutions and the decrease in thickness measured as well as appearance observed after that time. Table XIX gives the principal results of these tests.

A mixture of concentrated  $H_2SO_4$  and  $HNO_3$  scarcely attacks duralumin, nor does concentrated  $H_2SO_4$  containing some dissolved  $K_2Cr_2O_7$ ; the latter is recommended as a cleansing solution for duralumin vessels.

<sup>1</sup>Private communication from The Aluminum Castings Company, through Prof. Jeffries.

Some tests made at the shipbuilding docks of Vickers Ltd., Barrow-in-Furness, indicate that duralumin in the hardened condition resists the action of sea-water very well indeed. Four strips, one foot square, were hung on the ways such that at low tide they were above the water level, at high tide, immersed. After six months the losses in weight and thickness were as follows:

| No.    | Loss in Weight<br>Gram per Sq.Cm. | Loss in Thickness<br>in Cm. |
|--------|-----------------------------------|-----------------------------|
| 1..... | 0.00105                           | 0.00038                     |
| 2..... | 0.00107                           | 0.00039                     |
| 3..... | 0.00045                           | 0.00016                     |
| 4..... | 0.00062                           | 0.00023                     |

The Luftschiffbau-Zeppelin-Gesellschaft exposed angles and U-profiles of duralumin, copper, iron, aluminium alloys, pure aluminium, and elektron to the action of sea air and spray on a light-ship in the North Sea for three months. These sections were also riveted and screwed together. Duralumin resisted these conditions

Fig. 25—Increase of Hardness of Duralumin by Cold Working (Cohn, 471, 473). 1. Tensile Strength and Elongation of Hardened Duralumin. 2. Same for Rolled But Not Hardened

better than any of the other materials (Cohn—*loc. cit.*), and showed practically no oxidation.

Investigation has also been made of the alteration in mechanical properties of duralumin brought about by exposure to corrosion. It is known that some alloys of aluminium and aluminium itself often suffer deterioration in this manner. The Dürer-Metallwerke A. G. exposed bars and wire of different sizes of duralumin on the roof of one of their buildings for two and one-half years. Samples were tested from time to time and within that period no evidence of any alteration in hardness or ductility was shown. Evidently the properties of this material acquired by hardening are quite stable.

There are described below some tests on the stability of aluminium alloys, including duralumin when tested in a corroding medium.

From the foregoing paragraphs it is seen that duralumin has been subjected to rather extensive and severe tests covering its properties and their stability under different conditions. It is apparently a most excellent material for construction purposes, for the production of structural members, for forgings and for tubes, bars and wire.

It is possible to weld duralumin in the same manner as pure aluminium. The joint is not as strong as the

original material, however, since the heat of welding destroys the properties produced therein by hardening. By cooling the joint rapidly after welding some improvement may be made. For the present therefore construction work with duralumin may best be done by riveting or other mechanical forms of jointing work.

In table XX are given the physical properties which may usually be obtained for duralumin in different forms.

## MISCELLANEOUS ALLOYS

In the foregoing paragraphs have been described those alloys which have been used commercially to some extent. There are described in the patent and periodical literature almost as many light aluminium alloys as there have been investigators interested in them, and it would be useless to attempt to enumerate all of them. In table XXI however is given a list of many of them, together with whatever information is known about them. The numerical values given in this table are merely those published and are not guaranteed.

A list of patents covering light aluminium alloys, complete for the United States and incomplete for other countries, is given in Table XXII.

The alloys of magnalium have been studied by Mach (Krause, p. 107).

The alloys of aluminium, zinc and magnesium have been studied by Murmann (Krause, p. 108).

D. R. Patent 231,060, 1909, describes the properties of alloys of aluminium, copper, manganese and silver  
D. R. Patent 242,313, 1911, describes the properties of alloys of aluminium with cobalt and tungsten.

Rübel (Krause, p. 129) describes the properties of alloys of aluminium with phosphorus.

Borchers (Krause, p. 130) describes the properties of aluminium to which cerium has been added. This metal is a good deoxidizer and fluxes for aluminium, and is said to reduce its content of silicon.

Uyeno (Krause, p. 132) describes alloys of aluminium with mercury and zinc which are used to generate hydrogen (with hot water) for balloons.

## X. PHYSICAL PROPERTIES OF LIGHT ALLOYS

Besides the usual mechanical properties of alloys, the engineer (particularly the aircraft engineer) is interested in (1) the effect of temperature on the mechanical properties of the light alloys, and (2) the thermal conductivity of casting alloys (motor pistons).

Besides the tests by Rosenhain and Archbutt on aluminium-zinc alloys (438), some of which are described above, and those on duralumin by Cohn (476), (described above), no results of tensile tests of light alloys at high temperature have been published. In general, however, a light alloy to withstand high temperatures should be made with a metal or metals of high melting point, such as iron, manganese, or nickel. An alloy contain-

TABLE XXI—MISCELLANEOUS LIGHT ALLOYS

ing somewhat more copper than No. 12 is manufactured by the Aluminum Castings Co. for service at elevated temperatures, for pistons etc. Much information covering both topics mentioned above is to be found in recent confidential military reports.

The alloys of magnesium and aluminium have attained some recognition as suitable for large optical mirrors. Mach and Schumann (290) have studied the adaptability of these alloys for this purpose and find that the alloy containing the compound  $Mg_3Al$ , is the best of the series. It is hard, and when polished has a reflecting power equal to or better than a silvered glass mirror. Special precautions must be taken to prevent the formation of blowholes; this is done by melting under a flux of salts, preventing the absorption of gas.

#### XI. CORROSION, DISINTEGRATION AND DETERIORATION OF ALUMINIUM AND ITS ALLOYS

The subject of the deterioration of aluminium and its alloys in service has naturally been of the greatest interest to the metallurgist and engineer alike; unfortunately it must be admitted that insufficient investigation has been made of the various rather obscure phases of it that some of the observed phenomena may be regarded as in any sense solved.

It may be preferable to distinguish four types of deterioration of aluminium alloys.

**Corrosion.** The corrosion, uniform or local, of the metal and its alloys is discussed above insofar as it has been investigated. An adequate direct comparison of the corrodibility of the various commercial casting alloys has never been made, although such information would be quite valuable, particularly to airplane designers and naval architects.

The following table gives an approximate comparison of the behavior of different alloys in sea water:

|                                                    | Loss of Weight in Sea Water<br>Lb. per Sq. Ft. per Month |
|----------------------------------------------------|----------------------------------------------------------|
| Rollad aluminium-copper alloys: 0 to 8 per cent Cu | 0.008 - 0.003                                            |
| Chilled cast aluminium-copper-manganese alloys: .. | 0.0004                                                   |
| Sand cast aluminium-zinc alloys: ..                | 0.001 - 0.002                                            |
| Duralumin sheets: ..                               | 0.0009 - 0.002                                           |
| Muntz metal: ..                                    | 0.0023                                                   |
| Naval brass: ..                                    | 0.0012                                                   |
| Mild steel: ..                                     | 0.0022                                                   |

When it is considered that the loss of volume of the light alloys per unit loss of weight is about 2.8 times that of brass or steel it is realized that particularly the copper and the zinc alloys cannot be used in sea water without some protective coating. The corrosion of alloys is in many cases not such a serious matter as they may be effectively protected from corrosion in most cases by a varnish or paint.

**Cracking.** Many cases of mysterious cracking of aluminium alloy castings, particularly of the zinc-

aluminium type, are undoubtedly due to shrinkage cracks originating during the solidification of the casting. It is well known that all aluminium alloys are fragile at temperatures just below the melting point or range; cracking due to faulty moulding or hard ramming is generally visible in the finished castings, but invisible and interior cracks are often formed which open up subsequently when stress is applied. The remedy for such defects lies of course only in better foundry and casting designing practice and in the use of alloys of least fragility at these temperatures. It is the consensus of opinion of foundrymen that zinc-aluminium alloys are inferior to aluminium-copper alloys in this respect. The addition of copper to alloys containing zinc materially improves this condition.

**Disintegration.** The spontaneous disintegration of alloys of aluminium with high percentages (50 per cent and more) of iron, manganese, nickel has been noted by investigators (Hindricks). These alloys when cast are hard and brittle but upon standing actually fall to powder.

The same type of phenomenon is observed in the case of aluminium-zinc alloys containing 50 per cent zinc and more (Pack, 302, Williams, 295). Such alloys annealed after casting are sound and dense, but upon standing (under no stress) particularly when exposed to slightly higher temperatures and moist air, swell and warp; cracks appear in the castings.

The final explanation of these changes has not been given; in fact the data are still discordant. Rosenhain and Archbutt (see above) found no evidence whatever of deterioration within ten months in sand-cast aluminium-zinc alloys containing up to 75 per cent of zinc. The changes which occur are due probably either to some change in constitution progressing in the alloy, or to differences in the coefficients of thermal expansion of the different constituents of the alloy. These changes have also been somewhat vaguely ascribed to the presence of impurity in the alloy (see discussion on Rosenhain-Archbutt paper, 438).

**Corrosion and Stress.** Under this group are considered some very interesting cases of deterioration due to the combined effect of stress and corrosion.

The experiments of Heyn and Bauer (130) have been described above, in which it was found that cold-rolled or hard aluminium sheet is exfoliated and blistered badly during corrosion in certain solutions, whereas the same material, annealed, corrodes quite uniformly in the same solutions. The effects of initial stress on the electrolytic solution of the metal and of the relief of initial stress by corrosion combine to produce this unusual phenomenon.

Somewhat more recently investigation has disclosed the fact that the tensile properties of hard drawn bars of an aluminium-zinc-copper alloy are very unfavorably affected by simultaneous corrosion (Cohn, 476). His results, obtained on an alloy of the following composition:

|           | Per Cent |
|-----------|----------|
| Zinc      | 9.40     |
| Copper    | 0.32     |
| Magnesium | 0.39     |
| Aluminium | balance  |

in the form of extruded (?) bars are given in Table XXIII.

It is noted that in the hard or cold-worked condition the alloy gave a much less ductility and strength when

TABLE XXIII—EFFECT OF STRESS AND CORROSION ON TENSILE PROPERTIES OF ALUMINIUM ALLOYS  
(Cohn, 471,473)

|                                                                 | 20—air.....                                                            |                                                                                         | 76,000                            | 6 1                          |                                   |
|                                                                 | 20—water.....                                                          |                                                                                         | 75,100                            | 6 9                          |                                   |
|                                                                 | 70—water.....                                                          |                                                                                         | 72,800                            | 5 5                          |                                   |

(1) Broke outside of gage length.

tested in water than when in air. After annealing this effect was reduced. Duralumin showed practically no sensitivity to such treatment either as heat-treated or as heat-treated and cold worked.

These experiments were undertaken in order to explain the cracking which had been noticed of sections, rods and tubes of this commercially much used alloy when stored and under no stress. Similar experience has been recorded in the case of the breaking and em-

both steel and wood in construction in which both strength and lightness are a prime requisite.

XIII. HEAVY ALUMINIUM ALLOYS

The use of aluminium as an alloying element is perhaps as extensive in alloys containing an excess of other metals as in the light alloys.

Alloys of from 3 to 10 per cent of aluminium in copper are manufactured in both the cast and in the rolled

Fig. 26—Effect of Annealing Duralumin (Cohn, 471, 473). 1. Tensile Strength; 2. Elongation. Sample Annealed and Cooled in Air

Fig. 27—Effect of Temperature on Physical Properties of Duralumin (Cohn, 471, 473). 1. Tensile Strength; 2. Yield Point; 3. Reduction of Area; 4. Elongation.

brittling of hard-drawn aluminium wire electric conductors.

XII. COMPARISON OF DENSITY AND MECHANICAL PROPERTIES OF ALUMINIUM ALLOYS WITH OTHER MATERIAL OF CONSTRUCTION

In Table XXIV are compared the tensile properties for several materials used for construction in relation to their densities. Steels have been chosen for comparison which have approximately the same ductility as the duralumin. Douglas fir has been included as representing the best wood available for aircraft wood construction. The values given bring out the fact that, weight for weight, duralumin and similar light alloys are as strong as the best steels and for the same strength give greater stiffness. There appears to be no doubt of the adequacy of such light alloys as substitutes for

or wrought form under the name of aluminium bronzes. The properties of these alloys are described by Corse and Comstock (478), Corse (482), Read (490), Carpenter and Edwards (380), and many others.

An aluminium bronze containing 10 per cent of aluminium will have the following tensile properties when cast to size (478):

Tensile strength, lb. per sq.in.....75,000  
Elongation in 2 in. per cent..... 24

A modification of this alloy containing 10 per cent of iron, 10 per cent of aluminium and treated with titanium will give the following tensile properties when cast to size:

Tensile strength, lb. per sq.in.....80,000  
Elongation in 2 in. per cent..... 30

Aluminium bronze for rolling containing usually

| Douglas fir (4).....                           | 0 47                    | 1 64 x 10 <sup>6</sup>                | 6,100 (3)                        | 4,400                       | ..                             | ..                           | 1,200 (3)                      | 13,000                           | 2,500                          | 0 47         | 0 89                                                                                                                                                       | 21 10           |

(1) Containing 25 per cent Zn, 3 per cent Cu, (a) in form of 4-in. hot-rolled bar (Rosenhain-Archbutt) ———, (b) as rolled 0.156 in. diameter sheet, annealed.

(2) Using working stress of  $\frac{\text{yield stress}}{2}$ .

(3) Adopted by American Railway Engineering Association.

(4) These values are determined in the transversal bending test.

about 7.5 per cent of aluminium. This alloy when rolled will give the following approximate values of the tensile properties:

Tensile strength, lb. per sq.in. .... 80,000-90,000  
Yield point, lb. per sq.in. .... 15,000-20,000  
Elongation in 2 in., per cent. .... 20-30

Aluminium is extensively used as a deoxidizer in both iron, steel and non-ferrous metals, and also in the manufacture of steel to produce blowhole-free ingots of steel. Brinell (479) finds that this effect of aluminium preventing blowhole formation in acid-steel ingots is about 13 times as great as that of silicon and about 90 times as great as that of manganese. He gives the formula

$$D = Mn + 5.2 Si + 90 Al.$$

If  $D = 2$ , blow-hole-free acid steel ingots are produced 24 by 24 cm. when poured into an almost cold iron mold, 5 cm. thick.

#### XIV. SPECIFICATIONS FOR ALUMINIUM AND ITS LIGHT ALLOYS

There are given below references to published specifications for commercial aluminium and its light alloys.

##### A. Aluminium.

(a) Ingot aluminium, U. S. Navy Department, No. 47A1a, 1915. International Aircraft Standards Board, No. 2N1, 1917.

(b) Aluminium sheet, International Aircraft Standards Board, No. 3N12, 1917.

(c) Aluminium bars, International Aircraft Standards Board, No. 3N23, 1918.

(d) Aluminium tubes, International Aircraft Standards Board, No. 3N20, 1917.

##### B. Aluminium alloys.

(e) No. 12 casting alloy, Society of Automotive Engineers, No. 30, 1912. International Aircraft Standards Board, No. 3N11, 1917.

(f) No. 31 casting alloy, Society of Automotive Engineers, No. 31, 1912.

(g) Casting alloy, U. S. Navy Department, No. 49A1, 1915.

(h) Duralumin sheet, International Aircraft Standards Board, No. 3N16, 1917.

(i) Duralumin bars, International Aircraft Standards Board, No. 3N18, 1918.

(j) Duralumin tubes, International Aircraft Standards Board, No. 3N17, 1918.

### Thick Deposit of Electrolytic Nickel

Among the interesting exhibits at the recent Chemical Exposition was one which should have been marked with the "bull's eye" to indicate that it represented manufacture since the war. This comprised a number of shapes of pure electrolytic nickel which had been deposited on molds to a thickness of as much as one-eighth inch. Heretofore electroplaters had considered it impossible to make satisfactory nickel plate thicker than 0.001 to 0.002 of an inch in thickness because heavier plates were brittle and porous and tended to scale from the metal on which they were deposited. According to the new process represented in the exhibit, and which is the invention of Mr. C. P. Madsen, a dense deposit can be made practically as thick as desired. The process is an excellent example of the art of galvanoplasty, or the production of articles by electrodeposition on molds, which has been used rather extensively in Europe for manufacture of copper articles such as tubing. It has not found extensive commercial development in this country.

The nickel deposited by the Madsen process is homogeneous and malleable, showing a surface free from pits or roughness. In its physical properties it is comparable to rolled nickel, having a tensile strength of 62,000 pounds per square inch with an elongation of 20 per cent. It is impervious even at a pressure of 850 pounds per square inch when the wall of the vessel is but 20/100 of an inch thick. The nickel can be deposited in forms which are now spun or drawn, but more particularly in intricate forms which it is not possible to make by any other known means. Its cost is low because forms can be deposited direct from an impure anode or even from salts in solution. The cost for articles that can be spun is less than by the spinning process on account of the high cost of preparing sheets for the latter method. Since the Madsen nickel has a purity of 99.8 per cent it possesses valuable properties for chemical purposes. On account of the military value of the process it is impossible to give many details but it is the desire of the Government that some publicity should be given to the matter in order that those who might make use of it will know of its existence. Correspondence can be directed to Dr. F. G. Cottrell of the Bureau of Mines, Washington, D. C., and Mr. C. P. Madsen, 44 Walnut St., Newark, N. J.

## Personal

MR. A. W. AMBROSE, acting chief petroleum technologist of the U. S. Bureau of Mines, is spending a few weeks in California on investigations in connection with the work of the Bureau. MR. C. H. BEAL, petroleum technologist of the Bureau, is taking Mr. Ambrose's place during his absence from Washington.

MR. HARRY L. BARNITZ, formerly sales agent for the International Oxygen Company, has severed his connection with that firm and is engaged in consulting engineering in matters relating to oxygen and hydrogen.

MR. A. E. DRUCKER is now connected with the firm of Howard Morinni & Co., Inc., at 111 Broadway, New York City, as manager of their chemical and metallurgical departments.

MR. FRANK P. FAHY, consulting magnetic engineer, Hudson Terminal Building, New York City, has been awarded the John Scott Legacy medal and premium for the development of the Fahy permeameter, by the City of Philadelphia, which acted upon the recommendation of the Franklin Institute.

MR. CLAUDE FERGUSON has resigned as superintendent for the Copper Queen Gold Mining Co., at Stoddard, Arizona, to accept a similar position with the Consolidated Arizona Smelting Co., in charge of the operation of the De Soto and Swastika mines.

PROF. V. H. GOTTSCHALK, formerly professor of chemistry at the Missouri School of Mines and Metallurgy, has been appointed director of pure research for the American Cotton Oil Co. and subsidiaries. His headquarters are at Chicago.

MR. WILLIAM H. HAMPTON has been placed in charge of and development of miscellaneous gas defense apparatus under Major Waldemar Kops, Gas Defense Division, Chemical Warfare Service, U. S. A., Long Island City.

MR. W. W. JONES, formerly manager of the New York office of Frederick Stearns & Company, has accepted the appointment of manager of the essential oil and gum department of the National Aniline & Chemical Company, Inc., 21 Burling Slip, New York.

MR. R. V. MILLS, petroleum technologist of the U. S. Bureau of Mines, with headquarters in San Francisco, is at present in West Virginia where he will be engaged in Bureau work for several months.

MR. C. C. O'LOUGHLIN, formerly with Braum-Knecht-Heimann of San Francisco, has joined the sales force of the Hoskins Mfg. Company of Detroit.

DR. E. C. SHOREY has resigned from the Division of Chemical Investigation in the Bureau of Soils, U. S. Department of Agriculture, to accept a position at the Marcus Hook, Pa., plant of the National Aniline and Chemical Co.

MR. H. E. SHRIVER, has accepted a position as chemical engineer with the Air Nitrates Corporation at their electrochemical plant at Muscle Shoals, Ala., in a supervisory position in Unit 5. He was formerly assistant chemist, South Carolina Experiment Station, Clemson College, S. C.

MR. PAYNE G. WEST has been appointed assistant manager of field sales for the Lakewood Engineering Company of Cleveland. He was formerly associated with the T. L. Smith Co., Milwaukee, as sales manager.

MR. O. L. THOMAS is now at the U. S. Government powder plant at Jacksonville, Tenn., as chief supervisor of caustic soda manufacture and soda ash recovery, having been transferred from the Experimental Station of E. I. duPont de Nemours & Co., Wilmington, Del.

## Book Reviews

**CRUDE RUBBER AND COMPOUNDING INGREDIENTS.** A text book of Rubber Manufacture. By Henry C. Pearson, Editor of the *India Rubber World*. Third Edition, 1918. New York: The India Rubber Publishing Co. Price \$10.00.

A practical book of information on rubber manufacture written by a practical man for the benefit of men actively engaged in the production of rubber goods. It can hardly be classed as a scientific work, nor is it aimed at the rubber chemist though he may get many valuable ideas from it. The book is well written and is readily understandable by any one with ordinary intelligence. It includes many old and time-tried ideas, some of which have been found unworkable, but on the whole it teems with suggestions for the man who faces the every-day problems of rubber production and research.

The following is a brief review of its contents:

CHAPTER I. Deals with the nature of rubber, botany of the various rubber vines and trees, and gives the origin of many commercial varieties. Both the wild and plantation rubbers are briefly covered. The writer emphasizes a fact often lost sight of which is the most characteristic if not the most important property of rubber, i.e., "it can be repeatedly stretched to many times its length, returning each time to about its first dimensions." He still holds to the old fashioned idea that rubber is composed of an adhesive principle which is readily soluble and a nervy insoluble substance which gives rubber its elasticity. Most modern rubber chemists believe that rubber exists in different degrees of polymerization and that there is no such thing as a soluble and an insoluble portion. It is to be regretted that no analytical data are given for the different rubbers.

CHAPTER II. Contains a rather good description, botanically and chemically, of some little known rubbers and pseudo gums; particularly interesting to one working with adhesive problems.

CHAPTER III. Deals with methods of coagulation. A brief review of the steps in coagulation and many different processes which have been advanced at one time or another.

CHAPTER IV. Vulcanizing processes, ingredients, and the optimum cure. The author does not restrict himself to sulphur and sulphur chloride, but gives a number of processes which were advanced at the time the rubber industry was trying to get around Goodyear's patents. One or two purely trade preparations are given without mention of their composition, maker, or any information which would allow one to duplicate or even obtain them. The work of Eaton and Grantham on the optimum cure is briefly reviewed.

CHAPTER V. A review of the literature on organic and inorganic accelerators from the standpoint of the practical rubber man. The author states that mineral accelerators undergo no chemical change during vulcanization, which is incorrect. Nothing is given on the preparation nor chemical structure of the various organic accelerators.

CHAPTER VI. An excellent review of various inorganic fillers. Would have been more valuable to the chemist if a little more analytical data had been given. In the opening paragraph the author is not sufficiently definite as to the purpose of compounding which is not adulteration of the rubber but is practised chiefly to bring out certain desirable properties such as strength, elasticity, toughness, etc., which render the product superior to anything found in nature. Both gas-black and zinc oxide which are the most important and valuable fillers known today are placed among the pigments.

CHAPTER VII. A review of practically all the rubber substitutes which have been advanced within recent years. Many are absolutely worthless and unworkable, but the chapter will prove of value to the investigator who seeks ideas.

CHAPT. VIII. A very good review of hard rubber and gutta percha substitutes, including cellulose products. A collection of useful information.

CHAPT. IX. Deals with resins, balsams, etc., many of which have been used at one time or another in rubber compounding.

CHAPT. X. An excellent survey of the pigments used in coloring rubber. More analytical data would have been desirable.

CHAPT. XI. Acids, alkalis, and their derivatives used in rubber manufacture. Information for the rubber man who has had no training in chemistry.

CHAPT. XII. Vegetable and other oils at one time used with rubber. Many of those given are now obsolete.

CHAPT. XIII. A review of rubber and resin solvents. Several trade preparations are given space without mention of their composition, etc.

CHAPT. XIV. A survey of miscellaneous processes used in factory practice, many of which are not to be found elsewhere.

CHAPT. XV. Synthetic rubber. A review of Luff's paper in the *Journal* of the Society of Chemical Industry. It is not sufficiently definite and is handled without structural formulae. It is intended for the non-technical man.

CHAPT. XVI. A review of Ostromislensky's work on vulcanization; rather a complete abstract.

CHAPT. XVII. The general business of reclaiming is briefly described and a number of individual processes are mentioned. It is to be regretted that patents and other references are not given.

CHAPT. XVIII. Deals with the testing and analysis of crude and vulcanized rubber. A number of specifications, various standard methods of testing, and analysis are given in detail.

CHAPT. XIX. A brief survey of the methods of preparation of rubber for use. A number of typical compounds are given. These have no practical value and many of the rubbers called for are no longer obtainable. They do not represent modern compounding practice.

CHAPT. XX. Treats of Gutta-Percha and Balata, and is very well done. The information given is of considerable value.

The volume is what the author intends—a practical book on rubber for the practical man.

\* \* \*

THE FERTILIZER HAND BOOK. 456 pages. Price \$1.50. Philadelphia: Ware Bros. Company.

The eleventh edition of this handbook is now ready. The trade statistics include everything on fertilizer given out by the Government. The list of fertilizer manufacturers includes over a thousand firms. The directories of the cottonseed oil mills and the packing and rendering establishments are brought up to date. The segregated sections are: A, fertilizer manufactures; B, allied directory—companies having products used in fertilizer, such as ammonia; C, phosphate rock; D, fertilizer machinery; E, raw materials, such as potash; F, fertilizer merchants; G, chemist and engineers; H, cottonseed oil mill equipment; and I, packers' and renders' machinery. Special articles written by specialists give interesting treatment on some major subjects, such as: "The Composition of Cottonseed" by Thos. C. Law; "The Use of Lime in Agriculture" by John H. Voorhees; "Potash in 1916-1917" by Hoyt S. Gale; "Sulphur and Pyrite in 1916" by Philip S. Smith; "Maintaining Fertility on Fertilizers Alone" by E. G. McCloskey; and "The Production of Phosphate Rock in 1916" by R. W. Stone.

\* \* \*

A DIRECTORY OF ENGINEERS. Published by the American Association of Engineers, Chicago, Ill. Cloth 6 x 9 in. Pages 192. Price \$2.00.

This directory gives a brief synopsis of each member's experience and training, which will be of definite usefulness to the employer of engineers, who will be able to tell whether an applicant fills his needs without the loss of time from unnecessary interviews.

The 2204 members registered in the Directory are divided according to experience, as follows:

|                                                       | Per Cent |
|-------------------------------------------------------|----------|
| Members having Civil Engineering experience.....      | 91.9     |
| Members having Mechanical Engineering experience..... | 24.8     |
| Members having Electrical Engineering experience..... | 12.8     |
| Members having Mining Engineering experience.....     | 5.7      |
| Members having Chemical Engineering experience.....   | 2.9      |

## Current Market Reports

### The Non-Ferrous Metal Market

**Monday, Oct. 7.**—The Government control over the metal markets is becoming more systematic. Elsewhere in this number the rules and regulations on platinum are printed, which give complete data for meeting any munition requirements that may arise during the present situation.

**Aluminum.**—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40 to 45c; sheet aluminium, 18ga. and heavier, 42c; powdered aluminium, 100 mesh, 70c.

**Antimony.**—The demand is quiet and prices have been on a slight decline at 13½c to 14c.

**Copper.**—The price of \$520 per ton for car load lots and 27.3c. per pound for small lots is expected to be continued at the conference to be held the latter part of this month.

|                                 |     |        |          |
|---------------------------------|-----|--------|----------|
| Copper sheets, hot rolled.....  | lb. | \$0.36 | —\$0.37½ |
| Copper sheets, cold rolled..... | lb. | .37    | — .38½   |
| Copper bottoms.....             | lb. | .44    | — .45½   |
| Copper rods.....                | lb. | .36    | — .37    |
| Copper wire.....                | lb. | .29½   | — .30    |
| High brass wire.....            | lb. | .28½   | — .29    |
| High brass sheets.....          | lb. | .28    | — .29½   |
| High brass rods.....            | lb. | .26½   | — .28    |
| Low brass wire.....             | lb. | .32    | — .34½   |
| Low brass sheets.....           | lb. | .32    | — .34    |
| Low brass rods.....             | lb. | .33½   | — .35    |
| Brazed brass tubing.....        | lb. | .37    | — .39    |
| Brazed bronze tubing.....       | lb. | .42½   | — .44½   |
| Seamless copper tubing.....     | lb. | .43    | — .45    |
| Seamless bronze tubing.....     | lb. | .45    | — .46    |
| Seamless brass tubing.....      | lb. | .37½   | — .39½   |
| Bronze (gold) powder.....       | lb. | 1.00   | — 1.75   |

**Lead.**—The lead market is limited by selling restrictions. Producers must sell at a uniform and pre-arranged price. In car load lots at East St. Louis, the price is \$155 per ton. In New York, all speculative and traders' lead has disappeared. The Lead Committee apportions lead at 8.05c. to legitimate consumers.

**Manganese.**—The scale prices on page 629 of *CHEMICAL & METALLURGICAL ENGINEERING*, June 15, prevail; the highest price per unit being \$1.35.

**Zinc.**—Spelter is declining slightly; New York delivery being quoted at 9.2 to 9.25c. for spot and October. East St. Louis quotations are \$174 to \$178, per ton in car load lots. Sheet zinc 15c. and zinc dust 300 mesh) 16c. per pound in 1600-lb. casts.

**Silver.**—The Government price of \$1.01½ is hoped to promote production. Exports to the orient and our film industry have created a growing demand.

**Tin.**—The market is awaiting further development on the inter-Allied conference on tin. The War Industries Board will soon announce regulation prices and control the distribution of our 80,000-ton allocation. Tin is priced at 80c. per pound nominally.

**Tungsten.**—The western producers of scheelite are reluctant in offering at \$25.50 per unit. High grade wolframite is bringing \$25. Off-grade ores vary from \$20 to \$24.

### OTHER METALS

|                |        |        |         |
|----------------|--------|--------|---------|
| Bismuth.....   | lb.    | \$3.50 | —\$3.65 |
| Cadmium.....   | lb.    | 1.50   | —       |
| Cobalt.....    | lb.    | 2.50   | — 3.50  |
| Magnesium..... | lb.    | 1.75   | — 2.00  |
| Mercury.....   | 75 lb. | 125.00 | —       |
| Nickel.....    | lb.    | 1.95   | —       |
| .....          | lb.    | .40    | — .43   |
| Iridium.....   | oz.    | 175.00 | —       |
| Palladium..... | oz.    | 135.00 | —       |
| Platinum.....  | oz.    | 105.00 | —       |

## The Iron and Steel Market

No decrease whatever in the War Industries Board's estimate of the steel requirements for the current half-year is in prospect as a result of the exhaustive study the Board has been making in the past few weeks of the steel supply in proportion to requirements in each of the important war activities. At no time has the Board made public the precise tonnage required by any activity, its statements always dealing with the total only, and it is quite possible that the amount of steel expected to be needed by some departments through the remainder of this year may have been reduced, but if so such reductions have evidently been balanced by increases in the requirements in other quarters.

A long list has been given out showing curtailments in commercial consumption of steel arranged with manufacturers of various wares, from clothes wringers to baby buggies and talking machines, but the tonnage involved in any item is not large, and the benefit to the prosecution of the war may be as great from the labor that will be saved from working up the material as from the saving of material itself. There are two exceptions to this general statement, referring to the tin-plate and agricultural implement industries. Early in September there was a ruling that the tin-plate industry should limit its production in the fourth quarter of the year to 70 per cent of its production in the fourth quarter of 1917, which it was estimated would save about 150,000 tons of steel, and negotiations have since been in progress between the Food Administration and the packers of various non-perishable food products looking to drastic curtailment in their consumption of tin-plate. As the manufacture of tin-plate is prohibited except on Government orders and for packers of food products, the prospect is that the output will actually prove to be much below the 70 per cent originally prescribed. The other tonnage exception to the conservation program, the agricultural implement industry, is estimated to consume 2,000,000 tons of pig iron and steel a year, and the industry is to curtail its consumption by 25 per cent for the twelve-month beginning October 1, as compared with the preceding twelve-month. Its operations for any particular portion of the twelve-month are not limited, except as material may not be received with the degree of priority accorded. Of the 500,000-ton saving expected, more than half is in pig iron, but this is practically equivalent to a corresponding saving in steel since for a long time past the production of steel has been limited by the supply of pig iron.

As to the quantity of finished rolled steel required by the entire war program, including essential commercial consumption represented in the preference list, during the current half year, the War Industries Board's original estimate, made early in July, was 20,000,000 net tons. By successive stages this was increased to 23,000,000 tons and afterward it was stated that the total might be closer to 25,000,000 tons. The Board first estimated the prospective supply at 16,500,000 net tons and then increased its estimate to 17,000,000 tons. Production during July, August and September was probably fully 9,000,000 tons, and for the fourth quarter an estimate of 10,000,000 tons seems conservative, barring accidents such as a breakdown in transportation. As the gap is hardly likely to be bridged by an unexpectedly large production or by a decrease in the estimated requirements, the determination as to what lines of consumption will receive steel and what lines will not appears to be left to the priority and preference system. As this would cut steel off entirely from some important lines of consumption it is possible that there will be more granting of individual priorities for specific lots of material in special cases.

It is known that there have been large increases in certain war steel requirements since the War Industries Board estimated the half-year's requirements at 23,000,000 net tons. General Pershing's requirements have been increasing almost constantly, particularly as to shells and rails. The Railroad Administration desires a larger tonnage of rails to the end of the year than was originally contemplated, and it desires the completion of the 100,000 freight cars ordered a few months ago to be expedited in

order to clear the way for additional orders. Incidentally, it contemplates a very heavy locomotive building program for 1919.

### PIG-IRON PRODUCTION

Pig iron production, in gross tons, in the first half of 1918 is officially reported as follows, production in 1917 being given for comparison:

|                             | 1st half<br>1917 | 2nd half<br>1917 | 1st half<br>1918 |
|-----------------------------|------------------|------------------|------------------|
| Basic .....                 | 8,620,604        | 9,051,058        | 8,617,692        |
| Bessemer and low phosphorus | 7,041,426        | 6,673,306        | 6,006,607        |
| Foundry and ferrosilicon    | 2,602,448        | 2,725,810        | 2,518,721        |
| Malleable .....             | 509,982          | 505,597          | 607,318          |
| Forge .....                 | 198,914          | 146,793          | 197,636          |
| Spiegel and ferro-manganese | 210,432          | 242,678          | 237,228          |
| All other .....             | 74,429           | 17,739           | 42,528           |
| Total                       | 19,258,235       | 19,362,981       | 18,227,730       |

The smallness of the production in the first half of this year furnishes no surprise, as the approximate total has been known for three months. The information furnished as to segregation by grades is altogether new, and has an important bearing upon the matter of steel supply. It is well recognized that production of steel hinges upon pig-iron supply, as many steel departments could make more steel if they had more pig iron, and it is pertinent to inquire why so large a tonnage of foundry and malleable iron has been made. The large production in the second half of 1917 may be passed over, with the observation that it might have furnished a reserve stock at the end of the year, and the production in the first half of this year is to be compared with the output in the first half of 1917, there being no decrease, when the output of basic iron was stationary and Bessemer decreased a million tons. There is good ground for holding that in the interest of the war program the consumption of pig iron by iron foundries could have been reduced in the interest of providing more pig iron for steel making, and it is to be hoped that if the matter has not been fully adjusted by this time it will now be taken firmly in hand.

Pig-iron production has been increasing, as the progress of the season brings lower humidity, and there are reports of better quality coke being received by furnaces. The Fuel Administration continues its strenuous efforts, begun early in September, to cause better coke to be made. Steel production is likewise increasing and the current month is expected to make a new record.

There is no steel market, as the steel mills are unable to take full care of priority orders, with an occasional stray shipment of preference steel, the latter in almost every instance being against very old orders. Class D steel is being booked to an extent by some mills, with the distinct understanding that there is no visible prospect of the order being filled during the war.

## The Chemical Market

**COAL TAR PRODUCTS:**—In the coal tar products, the situation underwent little change during the interval. Of the important crudes, phenol has been in better demand with prices having an upward tendency. Benzol however, has been one of the lagging items and its position has developed rather weak. Prices for most of the intermediates are firm except in a few instances where prices have advanced. Paratraniline is still urgently demanded, as is paraamidophenol, both the base and hydrochloride. The demand for dimethylaniline has not eased up in interest though stocks are seemingly becoming more scant which it can be stated applies to situation of the intermediates in general.

**Phenol:**—Stocks are apparently becoming depleted owing to the pressure of demand that has been in evidence during the past week. Interest is still persistent for export purposes and the local demand has increased to a very noticeable extent. Owing to the condition of their stocks some large manufacturers are unable to offer quotations and where offerings are made prices have been advanced 2c. to 3c.

**Benzol:**—Buying interest has been lacking for this item to a considerable extent and its position in the market is rather

weak for the past week. Stocks are reported to have accumulated in large quantities and prices for the material in tank cars have declined 1c. while the drum material remains at about the same level.

**Aniline Oil:**—A firming up situation has developed in this market and cheap stocks which were offered early in the week are seemingly no longer available and prices on the whole have advanced from 1c. to 2c. relative to seller.

**Aniline Salts:**—The undertone is firm and trading is reasonably active, with stocks in accordance with the consuming demand. Prices are quotably unchanged and remain at firm levels.

**Paranitraniline:**—The item continues to be the feature of the intermediates and no immediate encouragement is offered by manufacturers who apparently have more or less difficulty in fulfilling their contracts, and holders of spot material are exacting all sorts of prices.

**Benzidine:**—The volume of business passing is apparently having no effect on the available stocks, which are reported to be in good supply. The activity of the base material is more noticeable for export purposes while domestic consumption is fair and steady. Prices continue at the same firm levels.

**H. Acid:**—Producers are all sold up and very little supplies are available in the resale market. The situation on the whole is virtually nominal.

**Paranitrotoluid:**—Factors in this line continue to state they are all sold up, however frequent lots appears in the resale market and are held for rather high prices.

**Paratoluidine:**—The same position applies to this item, manufacturers are in no position to offer but are experiencing difficulty in fulfilling their contracts owing to the situation of crude material. Prices however remain firm at the former levels.

**Benzaldehyde:**—There is a strong demand for this item, but stocks of the various grades are only in small lots here and there. However for material that is offered there is a ready market but prices vary and the situation is in favor of the seller.

**Puro Amidophenol:**—The products of some new concerns have been offered for sale on the market, but the trade is awaiting the results of tests. However the more popular products which are mainly of a high grade are rather scarce and during the week were advanced in price.

**Phthalic Anhydride:**—Export interest is still very much in evidence and the product for local consumption is also in good demand. The situation of this market is very firm and prices remain at firm levels.

**Monochlorbenzol:**—The item is one of those which appears to be neglected and supplies are reported as plentiful. Quotations heard are subject to no change.

**HEAVY CHEMICALS:**—During the intervening period trading has been rather quiet and no very noticeable changes have set in, although it may be stated that the market on the whole is firm. Caustic soda and soda ash still maintain their prominence and the volume of business passing for these commodities is the feature of the market. The stocks of bleaching powder are no easier and there seems to be no limit in sight relatives to price and no encouragement is offered pertaining to a more liberal supply. Price changes for the week are not numerous; however where made tended toward upward levels. Stocks of the alums are more noticeably scarce, particularly the ammonia, and some sellers are holding at higher prices.

**Soda Ash:**—Unusual quantities of the material have been changing hands during the past two weeks and the position of the product in the market is very firm. Sales during the period included single bags at \$2.65 to \$2.70 in warehouse and double bags at western shipping point were sold for \$3.40 with sales of barrel material having been consummated at \$3.25. Single bags in New York were quoted at the close at \$2.65 to \$2.70 and in Troy single bags were held at \$2.70 with \$2.70 quoted in Philadelphia. Double bags were quoted at \$3.40 middle west, while at Chicago the material was held at \$3.45 and \$3.20 Painesville. The position of barrel material appeared to have been somewhat easier during the latter part of the week and some sales were passing a trifle lower than the market, at that

time. The various quotations on barrel material were as follows: New York \$3.25 and 3c. works, Chicago \$3.15 and in St. Louis prices were firm at \$3.10. Dense ash in bags were held at \$3.90 to \$4.00 which was also about the market position of the dense in barrels.

**Caustic Soda:**—The situation is causing considerable comment, due to the fact that during the previous week, interest in the item was not particularly noticeable, but a firming up set in and at the close some lively trading was in evidence. Prices advanced for the solid material from \$4.30 to \$4.50 with sales having been closed at the latter price. Material rolling to New York during the last week is said to have been of sufficient quantity for the consuming demand. Buyers were seemingly aware of the prevailing conditions and were awaiting developments before attempting to enter the market. Offerings however in the market were in fair quantities at prices ranging from \$4.40 to \$4.50 ex warehouse and \$4.40 works. The ground material was generally quoted at from \$4.30 to \$4.50 ex warehouse.

**Sulphuric Acid:**—The notable feature of this item and of great moment to the trade was the recent announcement of the War Industries Board relative to the maximum prices effective from September 30 to December 30 as follows: 60 degrees Baume \$16 per ton of 2000 pounds, 66 degrees Baume \$25 per ton of 2000 pounds, 20 per cent Oloum, \$28 per ton of 2000 pounds; f.o.b. at manufacturers' works in sellers' tank cars. All strengths less than 92 per cent H<sub>2</sub>SO<sub>4</sub> shall be calculated from the price for 60 degrees Baume. All strengths above 92 per cent H<sub>2</sub>SO<sub>4</sub> shall be calculated from the price for 66 degrees Baume. In carboys in carload lots one-half cent per pound extra. In carboys, in less than carload lots, three-fourths cent per pound extra. In drums any quantity one-fourth cent per pound extra.

The new prices came as a surprise to the trade and on the whole every one with the possible exception of the consumers is very unfavorably disposed to the new schedule. Some acid manufacturers, whose equipment was not up to the latest specifications, found considerable difficulty in producing and making a fair profit under the previously fixed prices and it looks as though some of these plants will be compelled to suspend operations or in the event of the government insisting upon a production it will of course be necessary to obtain financial assistance from the War department. It is reported that one plant whose equipment was rather worn intended suspending operations after present raw materials were consumed but the government has the matter under reconsideration and it is believed that the plant will continue operations.

**Nitrate of Soda:**—The Chemical Alliance makes the following announcement: "We must again impress upon fertilizer manufacturers, particularly those operating sulphuric acid plants, the necessity for the conservation of their stocks of nitrate of soda. The mere fact that a company may have a liberal stock of nitrate of soda on hand should not be considered as an unlimited license to use it in mixtures or otherwise dispose of it. On account of the needs of the Government in its war program, very little encouragement is held out for any supplies of nitrate of soda for fertilizer manufacturers for spring use."

**Bicarbonate of Soda:**—No immediate relief is offered in the position of this item which continues to be in rather scant supply. The prices are firm and sales are passing at \$3.45 in carload lots. Offerings which appear on the market are readily bought up and quotations for October and November deliveries range from \$3.30 to \$3.40. Efforts on the part of buyers to cover at \$3.25 in New York were unsuccessful.

**Bichromate of Soda:**—Interests now concede that the position of this material is weakening and the cheap offerings which are placed on the market seemingly originate no activity. Sales that are consummated are closed on some low levels and prices now generally range from 23c. to 24c.

**Oxalic Acid:**—Trading is of a routine nature and the product on the whole is not in pronounced demand. Offerings which appear on the market seemingly constitute the only activity and prices range from 40c. to 42c.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, SEPT. 24, 1918

|                                                         |      |               |         |

| Tartaric, crystals.....                                 | lb.  | 1.70          | 1.75    |
| Tungstic, per lb. of W.....                             | gal. | 4             | .00     |
| Alcohol, sugar case, 183 proof.....                     | gal. | 91 1/2        | .92     |
| Alcohol, wood, 95 per cent.....                         | gal. | .69           | .69     |
| Alcohol, dehydrated, 180 proof.....                     | gal. | .69           | .69     |
| Alum, ammonia lump.....                                 | lb.  | .06           | .06 1/2 |
| Alum, chrome ammonium.....                              | lb.  | .18           | .20     |
| Alum, chrome potassium.....                             | lb.  | .20           | .22     |
| Alum, chrome sodium.....                                | lb.  | .12 1/2       | .13     |
| Alum, potash lump.....                                  | lb.  | .07 1/2       | .10     |
| Aluminium sulphate, technical.....                      | lb.  | .07 1/2       | .07 1/2 |
| Aluminium sulphate, iron free.....                      | lb.  | .03 1/2       | .04     |
| Ammonia aqua, 26 deg., carbonyl.....                    | lb.  | .08 1/2       | .09     |
| Ammonia, anhydrous.....                                 | lb.  | .12           | Nominal |
| Ammonium carbonate.....                                 | lb.  | .12           | .13     |
| Ammonium nitrate.....                                   | lb.  | (Fixed Price) | .15     |
| Ammonium sulphate domestic.....                         | lb.  | .07 1/2       | .08     |
| Amplac, white.....                                      | gal. | 5.30          | 5.35    |
| Arsenic, white.....                                     | lb.  | .09 1/2       | .13     |
| Arsenic, red.....                                       | lb.  | .65           | .70     |
| Barium carbonate, 99 per cent.....                      | ton  | 80.00         | 90.00   |
| Barium chloride, 97-98 per cent.....                    | ton  | 65.00         | 67.00   |
| Barium chloride.....                                    | ton  | 70.00         | 80.00   |
| Barium sulphate (Blanc Fixe, Dry).....                  | lb.  | .04 1/2       | .05     |
| Barium nitrate.....                                     | lb.  | .12           | .14     |
| Barium peroxide, basis 70 per cent.....                 | lb.  | .08           | .09     |
| Bleaching powder, 35 per cent chlorine.....             | lb.  | .05           | .05 1/2 |
| Borax, crystals, sacks.....                             | lb.  | .08 1/2       | .08 1/2 |
| Bromine, crude.....                                     | ton  | 65.00         | 70.00   |
| Bromine, technical.....                                 | lb.  | .07 1/2       | .08     |
| Calcium, acetate, crude.....                            | lb.  | .04           | .05     |
| Calcium, carbide.....                                   | lb.  | .10           | .10     |
| Calcium chloride, 70-75 per cent, fused, lump.....      | ton  | 22.00         | 24.00   |
| Calcium peroxide.....                                   | lb.  | .22           | .23     |
| Calcium phosphate.....                                  | lb.  | .09           | .09 1/2 |
| Calcium sulphate-98-99 per cent.....                    | lb.  | .08           | .09     |
| Carbon bisulphide, drums.....                           | lb.  | .08           | .09     |
| Carbon tetrachloride, drums.....                        | lb.  | .08           | .09     |
| Carbonyl chloride (phosgene).....                       | lb.  | 1.10          | 1.50    |
| Caustic potash, 88-92 per cent.....                     | lb.  | .45           | .77     |
| Caustic soda, 48 per cent.....                          | 100  | 4.25          | 4.40    |
| Chlorine, liquid (Government Purchase).....             | 100  | (Fixed Price) | .07 1/2 |
| Cobalt oxide.....                                       | lb.  | 1.60          | 1.65    |
| Coppers.....                                            | lb.  | .02 1/2       | .02 1/2 |
| Copper carbonate.....                                   | lb.  | .35           | .37     |
| Copper cyanide.....                                     | lb.  | .75           | .78     |
| Copper sulphate, 99 per cent, large crystals.....       | lb.  | .09 1/2       | .09 1/2 |
| Cream of tartar, crystals.....                          | lb.  | .80           | .85     |
| Epsom salt, heavy, U. S. P.....                         | 100  | 3.80          | 3.90    |
| Formaldehyde, 40 per cent.....                          | lb.  | .16 1/2       | .17     |
| Glauber's salt.....                                     | lb.  | .02 1/2       | .03     |
| Glycerine, bulk, C. P.....                              | lb.  | .63           | .65     |
| Iodine, resublimed.....                                 | lb.  | 4.25          | 4.30    |
| Iron oxide.....                                         | lb.  | .13           | .15     |
| Lead acetate, white crystals.....                       | lb.  | .17           | .17 1/2 |
| Lead arsenate (Paste).....                              | lb.  | .15           | .15     |
| Lead nitrate.....                                       | lb.  | Nominal       | .15     |
| Litharge, American.....                                 | lb.  | .12           | .14     |
| Lithium carbonate.....                                  | lb.  | 1.50          | 2.05    |
| Magnesium carbonate, technical.....                     | lb.  | .16           | .17     |
| Nickel salt, single.....                                | lb.  | .14           | .15     |
| Nickel salt, double.....                                | lb.  | .12           | .13     |
| Phosgene, (see Carbonyl chloride).....                  | lb.  | 1.10          | 1.50    |
| Phosphorus, red.....                                    | lb.  | 1.05          | 1.10    |
| Phosphorus, yellow.....                                 | lb.  | 1.10          | 1.20    |
| Potassium bichromate.....                               | lb.  | .45           | .46     |
| Potassium bromide granular.....                         | lb.  | .25           | 1.26    |
| Potassium carbonate, calcined, 85-90 per cent.....      | lb.  | .38           | .40     |
| Potassium chlorate, crystals.....                       | lb.  | .38           | .40     |
| Potassium cyanide, 98-99 per cent.....                  | lb.  | .60           | .70     |
| Potassium iodide.....                                   | lb.  | .75           | .80     |
| Potassium muric acid, 80-85 p. c. basis of 80 p. c..... | ton  | 300.00        | 350.00  |
| Potassium nitrate.....                                  | lb.  | .27           | .31     |
| Potassium permanganate U. S. P.....                     | lb.  | 1.85          | 2.00    |
| Potassium persulfate, red.....                          | lb.  | 2.25          | 2.50    |
| Potassium prussiate, yellow.....                        | lb.  | 1.00          | 1.10    |
| Potassium sulphate, 90-95 p. c. basis 90 p. c.....      | ton  | Nominal       | .14     |
| Rochelle salts.....                                     | lb.  | .42           | .48     |
| Salammoniac, gray gran.....                             | lb.  | .19           | .20     |
| Salammoniac, white gran.....                            | lb.  | 1.40          | 1.65    |
| Salt cake.....                                          | ton  | 22.50         | 25.00   |
| Silver cyanide, based on market price of silver.....    | oz.  | .63 1/2       | .64     |
| Silver nitrate.....                                     | lb.  | .63 1/2       | .64     |
| Soda ash, 58 per cent, light, flat (bags).....          | 100  | 2.60          | .00     |
| Soda ash, 58 per cent, dense, flat.....                 | 100  | 3.75          | 3.80    |
| Sodium acetate.....                                     | lb.  | Nominal       | .04 1/2 |
| Sodium bicarbonate, domestic.....                       | lb.  | .03 1/2       | .04 1/2 |
| Sodium bicarbonate, English.....                        | lb.  | .23 1/2       | .24     |
| Sodium bichromate.....                                  | lb.  | .25           | .27     |
| Sodium bisulphite, powd.....                            | lb.  | .12           | .14     |
| Sodium chlorate.....                                    | lb.  | .25           | .25 1/2 |
| Sodium cyanide.....                                     | lb.  | .30           | .35     |
| Sodium fluoride, commercial.....                        | lb.  | .17           | .18     |

|                                             |     |         |         |

| Sodium prussiate, yellow.....               | lb. | .39     | .40     |
| Sodium silicate, liquid (60 deg).....       | lb. | .03     | .04     |
| Sodium sulphate, 30 per cent, crystals..... | lb. | .07 1/2 | .08 1/2 |
| Sodium sulphate, 60 per cent, fused.....    | 100 | 1.05    | 1.15    |
| Sodium sulphate.....                        | lb. | .05 1/2 | .06     |
| Strontium nitrate.....                      | lb. | .25     | .30     |
| Sulphur chloride, drums.....                | lb. | .07 1/2 | .09     |
| Sulphur dioxide, liquid, in cylinders.....  | lb. | .15     | .40     |
| Sulphur, flowers, sublimed.....             | 100 | 4.39    | 4.50    |
| Sulphur, roll.....                          | 100 | 3.70    | 3.85    |
| Sulphur, crude.....                         | ton | 65.00   | 70.00   |
| Tin bichloride, 30 deg.....                 | lb. | .28     | .29     |
| Tin oxide.....                              | lb. | .18     | .20     |
| Zinc carbonate.....                         | lb. | .15     | .15 1/2 |
| Zinc chloride.....                          | lb. | .15     | .15 1/2 |
| Zinc cyanide.....                           | lb. | .13 1/2 | .14     |
| Zinc dust, 350 mesh.....                    | lb. | .12 1/2 | .14     |
| Zinc oxide, American process XX.....        | lb. | .12 1/2 | .14     |
| Zinc sulphate.....                          | lb. | .12 1/2 | .06 1/2 |

## Coal Tar Products (Crude)

|                                             |      |               |       |
|---------------------------------------------|------|---------------|-------|
| Benzol, pure, water white.....              | gal. | .23           | .28   |
| Benzol, 90 per cent.....                    | gal. | .25           | .25   |
| Toluol, in tank cars.....                   | gal. | (Fixed Price) | 1.50  |
| Toluol, for non-military use, in drums..... | gal. | (Fixed Price) | 1.55  |
| Xylol, pure, water white.....               | gal. | .45           | .45   |
| Solvent naphtha, water white.....           | gal. | .18           | .25   |
| Solvent naphtha, crude, heavy.....          | gal. | .12           | .15   |
| Cresol oil, 25 per cent.....                | gal. | .30           | .32   |
| Dip oil, 20 per cent.....                   | gal. | .30           | .32   |
| Pitch, various grades.....                  | ton  | 8.00          | 20.00 |
| Carbolic acid, crude, 95-97 per cent.....   | lb.  | 1.05          | 1.10  |
| Carbolic acid, crude, 50 per cent.....      | lb.  | .75           | .85   |
| Carbolic acid, crude, 25 per cent.....      | lb.  | .35           | .38   |
| Cresol, U. S. P.....                        | lb.  | .19           | .20   |

## Intermediates, Etc.

|                                    |     |         |         |
|------------------------------------|-----|---------|---------|
| Alpha naphthol, crude.....         | lb. | 1.00    | 1.10    |
| Alpha naphthol, refined.....       | lb. | 1.50    | 1.60    |
| Alpha naphthylamine.....           | lb. | .55     | .60     |
| Aniline, for drum extra.....       | lb. | .30     | .32     |
| Aniline salts.....                 | lb. | .44     | .45     |
| Anthracene, 80 per cent.....       | lb. | Nominal | .00     |
| Benzaldehyde (f.f.c.).....         | lb. | 4.25    | 4.50    |
| Benzidine, base.....               | lb. | 1.75    | .85     |
| Benzidine, sulphate.....           | lb. | 4.00    | 4.45    |
| Benzoic acid (U. S. P).....        | lb. | 2.90    | 3.00    |
| Benzoate of Soda, U. S. P.....     | lb. | 2.75    | 2.95    |
| Benzyl chloride.....               | lb. | 2.45    | 4.50    |
| Beta naphthol benzoate.....        | lb. | 10.00   | 12.00   |
| Beta naphthol, sublimed.....       | lb. | .75     | .85     |
| Beta naphthylamine, sublimed.....  | lb. | 2.65    | .15     |
| Dichlorobenzol.....                | lb. | 4.00    | 4.50    |
| Diethylaniline.....                | lb. | 4.00    | 4.50    |
| Dinitro benzol.....                | lb. | .36     | .38     |
| Dinitrochlorobenzol.....           | lb. | .40     | .45     |

## Plant Construction—Catalogs—New Publications

### Construction and Operation

#### Alabama

**NORTH BIRMINGHAM**—The Aetna Powder Co. will rebuild its plant recently destroyed by fire.

**SHEFFIELD**—The Sheffield Co. will build a filtration plant. Walter G. Kirkpatrick, Box 285, consulting engineer.

**SPRINGFORD**—The State Civil Department, Montgomery, will build water system; plans include the erection of a filtration plant and water mains here. Estimated cost, \$4,000. Sanitary Engineer Hazlehurst of the State Board of Health, Montgomery, in charge.

**TROY**—The Standard Chemical & Oil Co. will rebuild mill No. 2 recently destroyed by fire entailing a loss of \$60,000.

#### Arizona

**DOUGLAS**—The Empire Smelting & Refining Co. has applied to the city for a site for the erection of a smelter. Estimated cost, \$100,000. L. C. Barlow, manager.

#### Arkansas

**BATESVILLE**—The Blue Pig Mining Co. is in the market for a log washer for manganese and steam shovel engine, boiler, lumber, roofing, concrete, pump and pipe. Estimated cost, \$25,000. A. Besse, superintendent.

#### California

**MARE ISLAND** (Vallejo, P. O.)—The Bureau of Yards & Docks, Navy Department, Wash., D. C., plans to build an oxyacetylene generating plant here.

**SANTA BARBARA**—Winsor Soule, architect, 1206 E. St., is preparing plans for the construction of a 40 x 103 ft. reinforced-concrete laboratory building which will be donated to the Cottage Hospital Association.

**VICTORVILLE**—The United Tunstun-Copper Mines will build a mill at Piedmont in the Morongo District. Frank F. Peard, 30 Broad St., New York City, N. Y., president.

#### Georgia

**BRUNSWICK**—The Atlantic Refining Co., 314 E. Frank Ave., Philadelphia, Pa., will build an oil refinery here.

#### Illinois

**CHICAGO**—Swift & Co., 76 West Monroe St., will build a two-story, 15 x 50 ft. fatty acid building. Estimated cost, \$3,000.

**CHICAGO**—Wilson & Co., 41st and Ashland Ave. will build a three-story, 20 x 34 ft. fertilizer, dryer, and storage building. Estimated cost, \$65,000. C. P. Barnett, architect.

**DECATUR**—The Mueller Metal Co. will build a one-story, 200 x 300 ft. refining plant. J. H. Mueller and Cerro Gordo St. Adolph Mueller, president.

**GRANITE CITY**—The National Enamel-ling & Stamping Co. has awarded the contract for the construction of a one-story, 100 x 100 ft. brick building for steel line burning plant at the Unit Construction Co. Title Guarantee Building, St. Louis Mo. Estimated cost, \$75,000. Noted Aug. 31.

#### Idaho

**MALAD**—The California Sugar Manufacturing Co. will build a factory near E. A. F. Parkette 545 West 28th St., Orem, Utah, preparing plans.

#### Kansas

**BAXTER SPRINGS**—The Ladd Mining Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, ore bins, jigs, belts, lumber, roofing, engine, hoisters, track, ore cars, conveyors, air compressors, concrete motors, drills and hoisters. Estimated cost, \$60,000. J. L. Ladd, superintendent.

#### Kentucky

**LOUISVILLE**—The Magic Keller Soap Works, 1201 Story Ave., has awarded the

contract for the erection of additions and improvements to its plant to the National Concrete Construction Co., Board of Trade Building. Estimated cost, \$200,000.

**PRESTONBURG**—The Consolidated Oil & Gas By-Products Co. will build an alkali and gasoline plant here. A. B. Brodie, Huntington, general manager.

#### Massachusetts

**CHELSEA**—The Mexican Petroleum Co., Allens Ave., Providence, R. I., has awarded the contract for alterations to its oil plant to Ellis & Haugh Inc., 171 Westminster St., Providence, R. I.

#### Michigan

**DETROIT**—The Detroit Copper & Brass Rollings Mills, Clark Ave., will build an addition to its factory. Smith, Hinchman & Grylls, 710 Washington Arcade, architects.

**DETROIT**—The Michigan Smelting & Refining Co., 1635 Joseph Campau Ave., has awarded the contract for the erection of a factory and cold building to W. E. Wood Co., 1508 Ford Bldg. Estimated cost, \$100,000.

**WYANDOTTE**—The city will build a filtration plant to have a capacity of 12,000,000 gallons. Estimated cost, \$250,000. Winthrop R. Pratt, engineer.

#### Minnesota

**EVELETH**—The city will build two liquid chlorine plants. C. H. Williams, clerk.

#### Missouri

**ST. LOUIS**—The Dielectric Manufacturing Co., 224 South Vandeventer St., will convert two-story flat building into factory for the manufacture of chemicals and insulating material. Dr. J. J. Kessler, president.

**ST. LOUIS**—The Monsanto Chemical Works, 2nd and Lafayette St., will construct a plant for the manufacture of caustic soda and chlorine. John F. Queeny, president.

**MO. ST. LOUIS**—The Ordinance Dept., Wash., D. C., and the Mississippi Valley Iron Co., La Salle Bldg., are negotiating for the establishment of a pig iron plant here to include slake-making plant. Estimated cost, \$10,000,000. E. F. Goltra, president of the Mississippi Valley Iron Co., 6500 South Broadway, in charge.

**ST. LOUIS**—The United Brewing Co., Gravois and Michigan St., will convert its brewing plant into an oleomargarine factory and install new machinery in same. Total estimated cost, \$100,000. Otto F. Stifel, president.

**WACO**—The Cow Creek Mining Co., Carl Junction, will build a 200-ton concentration plant and is in the market for sludge and slime tables, crushers, boilers, motors, roofing, air compressors, pumps, conveyors and drills. Estimated cost, \$60,000. W. H. Clark, superintendent.

**MO. WACO**—The Freehold Oil and Gas Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, jigs, crushers, belts, engine, hoisters, lumber, roofing, motors, wiring, pipe, concrete and mill hardware. Estimated cost, \$65,000. W. S. Marquiss, superintendent.

#### Nebraska

**ANTIOCH**—The Sheridan Potash Co. has received authorization from the State Railway Commission to sell \$30,000 worth of the stock for the purpose of erecting a ten-ton plant on a lake northeast of Antioch. The lake contains about \$350,000 worth of potash.

**ANTIOCH**—The National Potash Co. will rebuild its plant recently destroyed by fire entailing a loss of \$300,000.

#### New Jersey

**NEWARK**—C. F. Massey, West Bank St., will build a one-story, concrete factory on the Passaic River, for the manufacture of concrete products. Estimated cost, \$15,000.

**PATERSON**—Francisco Santucci, 7 Passaic St., will build a one-story, 50 x 100 ft. brick dry-house at 9-13 Walker St. Estimated cost, \$10,000.

**RAHWAY**—The Philadelphia Quartz Co., Philadelphia, Pa., will build a large concrete and brick factory on a tract of 30 acres along the Central and Pennsylvania Railroads. Estimated cost, \$1,500,000.

#### New York

**ALBANY**—The Patent Vulcanatic Roofing Co., Tivoli St., has awarded the contract for the erection of a 1-story, 70 x 245 ft. factory addition, to the Hamilton Construction Co., Gay Building, Troy. Estimated cost, \$10,000. Noted Aug. 15.

**BROOKLYN**—The State Hospital Commission, Capitol Ave., Hopkiss, will build a sewage disposal system at the Creedmoor Division of the Brooklyn State Hospital. Estimated cost, \$25,000.

**BUFFALO**—The Metal & Alloy Specialty Co., 25 Illinois St., will build a foundry on Marion Ave. for brass, aluminum and other metal castings.

**BUFFALO**—The Prest-O-Lite Co., Speedway, Indianapolis, Ind., will build a charge-discharge plant on Erie St. Building and Tift St. consisting of four 1-story buildings.

**NEW YORK**—Charles Lane, 5 Beekman St., will build a 1-story, 56 x 100 ft. paper factory. Estimated cost, \$15,000. Dietrich Worthman, 114 East 28th St., architect.

**SALISBURY CENTER**—The Board of Supervisors of Herkimer Co. will build a 1- and 2-story brick hospital. Plans include the erection of a bacteriological laboratory. Total estimated cost, \$175,000. R. E. Ghyver, First National Bank Building, Herkimer, architect.

**NEW YORK**—The Rogers-Pvatt Shellac Co., 81 Water St., has awarded the contract for the erection of a one-story, 75 x 36 ft. concrete, brick and steel factory at 32-53 Essex St. to Isaac J. Hopper, 15 East 40th St. Estimated cost, \$25,000.

#### North Carolina

**CHARLOTTE**—Swift & Co., 76 West Monroe St., Chicago, Ill., has awarded the contract for the erection of a 1-story, concrete factory building for the manufacture of salad oil, to J. A. Jones, Realty Bldg. Estimated cost, \$75,000.

#### North Dakota

**GRAND FORKS**—The city will install a chlorine system of water purification. R. E. Murphy, of Wallace, Ternan & Co., superintendent.

#### Ohio

**CINCINNATI**—The American Smelting & Refining Co., 9th and Freeman St., will remodel three of its buildings for manufacturing purposes. Estimated cost, \$20,000. Baumschmidt & Drainie, Gerke Building, architect.

**CINCINNATI**—The Groves Fertilizer Co., Lockland, has awarded the contract for the construction of two additions to its plant: one, 3-story, 60 x 100 ft., mill construction, and other, 1-story, 60 x 200 ft., frame to the M. Marcus Building Co., 2030 Rounding Road. Estimated cost, \$50,000.

**PIQUA**—The city plans to build a water supply system including filtration station at Lorain Creek. Estimated cost, \$330,000. Albert Schroeder, City Building, director of public works, 1200 Whipple Fuller, 30 East 42d St., New York City, N. Y., consulting engineers.

**SANDISKY**—The Musterole Co., 1743 East 27th St., Cleveland, has awarded the contract for the erection of a 2-story, 60 x 70 ft. concrete and brick factory, to George Felek & Sons. Estimated cost, \$25,000.

**WARANA**—The United Paperboard Co., 171 Madison Ave., New York City, N. Y., will rebuild its 1- and 2-story, 70 x 360 ft. factory recently destroyed by fire. R. R. Owens, local manager.

#### Oklahoma

**CENTURY**—The Century Mining Co. will remove its concentration plant from Joplin to Century and remodel same: is in the market for sludge and slime tables, mill hardware, ore bins, ore cars, drills, air compressors, pumps, motors and electric wiring. Estimated cost, \$40,000. J. C. Trout, superintendent.

**DOOTHAT**—The Century Mining Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, jigs, lumber, roofing, conveyors, crushers, concrete, air compressors, belts, drills, cables, ore cars, ore cars, track incline, hoisters, track cross ties, etc. Estimated cost, \$65,000. Carl Scott, superintendent.

**HOCKERVILLE.**—The Diamond Joe Mining Co., Miami, Okla., will build a 200-ton concentration plant and is in the market for sludge and slime tables, jigs, drills, roofing lumber, engine, boilers, belts, concrete, hoisters, wire cables, air compressors and conveyors. Estimated cost, \$60,000.

**HOCKERVILLE.**—The Miami Volunteer Mining Co., Commerce, will build a 250-ton concentration plant and is in the market for sludge and slime tables, jigs, ore bins, ore cars, ore crushers, air compressors, belts and mill hardware. Estimated cost, \$65,000. Claude Holiman, superintendent.

**LINCOLNVILLE.**—The Canton Mining Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, ore bins, ore cars, cable, engine motors, belts, lumber, roofing, mill hardware, crushers, pumps, pipe, cement, air compressors, conveyors, drills and jigs. Estimated cost, \$60,000. Otis White, superintendent.

**MIAMI.**—The Right Good Mining Co., Ilathe, Kan., will build a 250-ton concentration plant and is in the market for sludge and slime tables, engine, boilers, pipe, pumps, conveyors, jigs, air compressors, crushers, mill hardware, motors, and slime tables. Estimated cost, \$60,000. C. H. Miller, manager.

**OKMULGEE.**—The city has awarded the contract for the erection of a sewage disposal plant and water-works system, to F. B. McCormick. Estimated cost, \$69,000. Noted July 30.

**PICHER.**—The Amy T. Mining Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, ore bins, ore cars, crushers, belts, boilers, engine, lumber, pump, motors, air compressors, pipe, pumps and jigs. Estimated cost, \$60,000. Ed. Ballinger, superintendent.

**PICHER.**—The LaSalle Mining Co. will enlarge its concentration plant to have a capacity of 500 tons, use electric motors instead of steam, and is in the market for motors, crushers, jigs, sludge and slime tables, mill hardware, electric wiring, air compressors, roofing, lumber, concrete, drills, belts, hoists, wire cables, scales. Estimated cost, \$100,000. C. L. Funk, superintendent.

**PICHER.**—The Oko Mining Co., Joplin, Mo., will build a 250-ton concentration plant and is in the market for jigs, crushers, rolls, lumber, concrete, roofing, engine, boilers, air compressors, conveyors and mill hardware. Estimated cost, \$65,000. A. Meyerhoff, superintendent.

**POTEAU.**—The American Indian Oil & Gas Co. will build plant to manufacture carbon from natural gas.

**QI'AT.**—C. F. Noble will build an absorption gasoline plant. Estimated cost, \$250,000.

**ST. LOUIS.**—The Prudential Mineral Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, conveyors, crushers, engine, belts, cable, lumber, roofing, concrete, track cars, cans and jigs. Estimated cost, \$60,000.

**TULSA.**—The Atlas Petroleum Co. will build a third unit to its 2-unit compression gasoline plant here.

## Pennsylvania

**HARMARVILLE.**—The La Belle Iron Works, Oliver Building, Pittsburgh, has awarded the contract for the construction of 12 mining buildings, and 200 brick houses, to the Thompson-Starrett Co., Second National Bank Building, Pittsburgh. Estimated cost, \$1,000,000.

**PHILADELPHIA.**—The Linde Air Products Co., 18th and Cambria Sts., has awarded the contract for the erection of a 1- and 2-story, 35 x 31 ft. manufacturing building, to W. W. Lindsay Co., Harrison Building. Estimated cost, \$63,000.

## Pennsylvania

**WARREN.**—The Union Petroleum Co. will build an oil refinery here. J. C. Kubler, in charge.

## Tennessee

**CHATTANOOGA.**—The Columbian Iron Works will rebuild its plant for the manufacture of shells recently destroyed by fire entailing a loss of \$100,000.

## Utah

**SALT LAKE CITY.**—The Burdett Oxygen Co., 363 Eccles St., will build an addition to its local plant to handle war contracts.

## Virginia

**CAMP STUART.**—The Construction Division War Department, Washington, D. C., will build laboratories, storehouses, nurses' infirmary, etc., at the base hospital here. Estimated cost, \$448,200.

**GRAHAM.**—The Pocahontas Manganese Corporation will build additions to its plant. The company recently increased its capital from \$25,000 to \$100,000.

**YORKTOWN.**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the erection of a fuel oil plant, with equipment, to the F. W. Mark Construction Co., Finance Building, Philadelphia, Pa. Estimated cost, \$500,000.

## West Virginia

**FAIRMONT.**—The Construction Division, War Department, has awarded the contract for the erection of a phosphorus plant near here, to the American Phosphorus Co., 3rd and Dauphin St., Philadelphia, Pa. Estimated cost, \$500,000.

**HUNTINGTON.**—The Northern Alkali & Chemical Co. will build a caustic potash factory to have an output of 1000 lb. daily, and is in the market for tanks, kettles and filter press.

**SPENCER.**—The International Gasoline & Oil Co., Fulton Building, Pittsburgh, Pa., will build a 1-story, 30 x 50 ft. gasoline refinery. Plans include the erection of a concrete engine house, compressor house, pump house, etc.

**SUTTON.**—The Sutton Chemical Co. will build a 1-story, 33 x 157 ft. chemical plant and a 1-story, 48 x 145 ft. retort house. Wm. McCabe, manager.

**WELLSBURG.**—The Eagle Glass & Manufacturing Co. has awarded the contract for the erection of an addition to its plant, to E. A. Crasman.

**WHEELING.**—The City Council will install a filtration plant, Chester & Fleming, Union Bank Building, Pittsburgh, Pa., engineer.

## Wisconsin

**BERON.**—The Consolidated Water Power & Paper Co., Grand Rapids, will build a 2-story addition to its paper mill here. L. A. DeGuere, Grand Rapids, architect.

**WAUWATOSA.**—The North Western Chemical Co., 61st and State St., will build a chemical plant. C. F. Ringer & Sons, University Building, Milwaukee, architect.

## Wyoming

**SUPERIOR.**—The Liberty Potash Co., will build a plant to extract potash from leucite rock, near here. C. R. Eastcourt, \$100,000. Guy Sterling, Newhouse Building, Salt Lake City, Utah, engineer.

## Canada

### British Columbia

**TRAIL.**—The Consolidated Mining and Smelting Co. will rebuild its roaster plant recently destroyed by fire entailing a loss of \$50,000.

### Nova Scotia

**WHYCOCONAGH.**—The American Syndicate has awarded the contract for the erection of a fire brick plant, to Wells & Gray, 701 Confederation Building, Toronto, Ont. Estimated cost, \$150,000.

## Ontario

**BRAMPTON.**—The city has awarded the contract for the erection of a sewage disposal plant, to G. C. R. Eastcourt, 250 Adelaide Ave., Toronto. Estimated cost, \$11,055. Noted Aug. 31.

**IAWKESEBURY.**—The Town Council has awarded the contract for the erection of a filtration plant, to Archambault & Leclair, 616 St. Denis St., Montreal, Que. Estimated cost, \$48,000.

**KIRKLAND LAKE.**—The Burnside Gold Mines, Ltd., is in the market for a ball mill, having a capacity of about 40 or 50 tons, electrical equipment, etc. C. A. Richardson, manager.

**LEASIDE.**—The Leaside Munitions, Ltd., will build a 2-story, 60 x 65 ft. plant here. Estimated cost, \$50,000.

**NEW TORONTO.**—The Village Council has awarded the contract for an extension to its filter house, to R. C. Hoffman.

**TORONTO.**—C. Goodman & Co., 76 Starford St., is in the market for a carbonizing machine capable of carbonizing anything from 100-300 pound batches.

**TORONTO.**—W. Harris & Co., Danforth Ave., has awarded the contract for the erection of a glue plant, to Archibald & Holmes, 36 Toronto St. Noted Aug. 15.

**TORONTO.**—Sanderson & Percy, 88 Adelaide St., West, will build a 1-story, addition to its factory, for the manufacture of paints and oil. Estimated cost, \$15,000.

## Saskatchewan

**ROSTERN.**—The Town Council will build a sewage disposal plant. Estimated cost, \$15,000. R. S. Pleury, mayor.

**SASKATOON.**—The Research Council will build a plant to experiment in producing gas from waste straw. Estimated cost \$15,000.

## Industrial Notes

**THE GOODYEAR TIRE & RUBBER COMPANY,** Akron, Ohio, have military training classes which have been in progress ever since our country's entry into the war. They have now been extended to include all inspectors and foremen, adding 1300 men to the ranks that had been taking advantage of the opportunity to acquire a comprehensive acquaintance with military tactics and practice.

This new feature is designed as a part of the regular duties of all inspectors and foremen during their regular working hours on Wednesdays and Fridays of each week, and applies to all alike, even to those holding military rank, except those being certified by the company's physicians.

Drills are held at Selberfield Field, the big athletic grounds of the company, under the supervision of the regular drillmaster and his corps of assistants. As the factory operates in three shifts of eight hours each, the drills are also conducted in shifts. Military drill has been popular at this plant, as is amply evidenced by the large numbers of employees that have voluntarily entered the various drill classes. These classes, however, have not been limited to classes for men, for a large number of girls have been drilling regularly ever since the army was first presented, and have become proficient in their military exercises.

The Goodyear Company now has an army of its own numbering 2000 some of whom will ultimately be called into their country's service, and when that time comes will be much better equipped than the raw material entering our training camps, without any previous training or military experience.

Many former employees who have received rapid promotions from the ranks as non-commissioned officers or have been highly recommended for commissions in the various officers' training camps, have written that in large part they owed their success to the previous experience they had received in the Goodyear drill classes. Some of these boys, who have received commissions in the army, have since had the pleasure of drilling the Goodyear classes, while home on furloughs.

It is the belief of the Goodyear officials that military training teaches accuracy, promptness, efficiency and discipline, and gives an all-around training to the body. An in the hope that these benefits might be shared in by its workmen, have placed at the doors of its workers opportunities to acquire them.

## Manufacturers' Catalogs

**THE CUTLER-HAMMER MFG. CO.,** Milwaukee, Wis., call attention to Publication 271 entitled "War-Time Control of Lights," Booklet F, August, 1918, on "C-H Iron-Clad Solenoids," which are particularly adapted for operating brakes used in connection with crane, elevator and hoist motors and Booklet G, August, 1918, on "Magnet-Operated Brakes for Direct Current Service."

**THE WALTER A. ZELNICKER SUPPLY CO.,** St. Louis, Mo., Bulletin No. 246, dated July 25, 1918, dealing with tanks they have in stock. Bulletin No. 247, August, 1918, on equipment and machine tools, for locomotives, cars, trucks, shovels, ditchers, loaders and loaders.

**THE WHEELER CONDENSER & ENGINEERING CO.,** Carteret, New Jersey: Bulletin 112-A on condensers, pumps, cooling towers, etc. There is a discussion in this bulletin entitled "Choice of Condensate," and also the remainder illustrates and describes other condensing machinery in detail.

## Steel Conditions

### After the War

RECENT diplomatic and military developments have not indicated when the war will end, but they have suggested quite clearly that when the war does end it will end much more suddenly than was previously assumed. As to conditions that will exist in the steel industry after the war, accordingly, there is marked out a special period of transition from war time conditions to the conditions that will exist for a period of years after the war. There has been much discussion as to the demand for steel that will exist for several years after the war, for reconstruction and other purposes, but it is now clear that there is to be an intermediate period of transition. Some of the foreign belligerents have adopted more or less explicit reconstruction programs, which may or may not function well at the outset, while the United States has adopted nothing, and has not even settled upon a basis on which a program can be constructed.

It is regarded as an item of progress that the authorities at Washington have let it become known, unofficially, that they purpose to retain, after a declaration of peace, some measure of the control they have exercised over industry during the war. We have become so accustomed to the issuance of orders and requests, and compliance therewith, that it is somewhat difficult to realize how different basic conditions will be when peace comes. The War Industries Board is constituted to exist for six months after peace is declared, but the continuance of its authority is another matter. For illustration, the board's regulation of steel prices is the result of an agreement between it and the producers of steel. If the steel producers had refused to agree to the fixing of maximum prices, the President had the authority of the act of June 3, 1916, "in time of war or when war is imminent" to fix fair prices at which the Government would buy, and there was also the prospect, in case an agreement could not be reached, of Congress acting, as it did in the Lever act in the case of "food, feed and fuel." None of this applies to the period after the war, while furthermore effective regulation would cover not merely maximum prices, as hitherto, but minimum prices also, for it is distinctly stated that the regulation contemplated is intended in part at least as a protective measure to manufacturers. An agreement among producers would be necessary, and interesting questions naturally arise as to the legality of such operations.

Apart from the very difficult subject of Government regulation there is the fact that a large part of the steel demand that has been banking up is demand for steel for construction purposes. The investor must have an

idea of the conditions likely to exist during the period of years in which the investment is to yield revenue and return the principal. He cannot be expected to act hastily. His buying of steel is not likely to be a factor in the transitional period. When the investor begins to buy, that will be a signal that the transitional period is over and that business has settled down to the work of the period of years in which the world will rehabilitate itself.

As to international trade in iron and steel no subject could well be more confused. There are wide divergences between the set prices for steel products in the United States and Great Britain, and there are wide divergences in the profits vouchsafed to manufacturers by these prices. That there will be great readjustments in costs goes without saying, but where they will tend to land the industries in the various countries, as to international competitive conditions, is a conundrum. If it is to be a case of *laissez faire* a period of years will be required for the adjustment.

The importance of the changes in international competitive conditions in iron and steel that will result from the rearrangement of the Minette ore field appears to have been magnified by many who have undertaken to discuss that subject. It has been formally announced at Washington that return to France of the portions of Alsace-Lorraine taken by the Germans in the settlement of the Franco-Prussian war is part of the American program, as it has been right along of the French program. Some observers in the past have ventured to assert, as an argument on this subject, that the Germans need the ore and the French cannot use the extra quantity, but it is not necessarily a part of the peace program that international trade in this ore be prohibited. It flourished before this war, in the form of a complicated interchange of self-fluxing and siliceous ores, and it can be established on new lines, calculated indeed to furnish an additional safeguard that Germany shall not make iron and steel for military purposes. Important as the Minette ores are, the entire region has furnished the basis for much less iron production by France, Belgium, Luxemburg and Germany than the production in the United States. The mere difference between the greatest production of pig iron in the United States before the war and the present rate of production is more than one-half the production of all countries credited to the use of Minette ore.

#### Help For the Gold Producer

TO POINT out the distressing situation of gold producers is becoming almost hackneyed. Apparently their metal is much in demand, yet its selling price may not be increased despite the small production. Thus gold is one commodity which falls without the scope of that trusty sheet-anchor, the Law of Supply and Demand. The profits of most of these producers steadily approach zero between the factors of diminishing ore tenure and increasing costs for labor, supplies and overhead. The situation is not local—from West Australia, South Africa and Canada comes the same plaint.

A well attended conference of Western producers, called by the Governor of Nevada, met at Reno in August. This meeting was a unit in asking for immediate relief and in condemning a change in price, but

unfortunately it was able to suggest no path out of this evident *cul-de-sac*. This is distinctly unfortunate. If they, who are vitally interested in the ways and means of gold production and acquainted with its importance to industry and finance, can suggest no sound workable method of relief, it is idle to expect politicians or others to study out the riddle. Thus it was that only the energetic propaganda of Western bankers succeeded in overcoming the general ignorance, suspicion and apathy of the recent meeting of the American Bankers' Association to a sufficient degree to have them refer the matter of gold supply to a standing committee for further investigation.

The Spokane Conference of Canadian and American producers held in September attempted to take this needed step in advance of its forerunner at Reno. After asking for a governmental investigation of the situation, it proposed several avenues of relief, any or all of which would be of material assistance. The exemption from assessment work, building of motor-truck roads, and extension of governmental credit would aid in the development of new producers and could readily be handled by a Minerals Administration. Priority of supplies, machinery and transportation and the allocation of labor can now be extended by existing governmental agencies in all countries, and in a very large number of cases would relieve the situation enormously. Under the circumstances it appears that an insistence upon these steps would be the best course of endeavor, since special class legislation toward pre-war freights and taxes would erect instant and powerful opposition.

It is unfortunate that after voting against a change in the present price, the conference fell into the inconsistency of proposing a bounty. One can hardly appreciate the specious arguments which led them to the delusion that a bounty is not tantamount to an increased price. Else in what currency are they to be paid? One flippantly might suggest that the bounty might be paid in zinc, thus coming to the aid of the zinc market at the same time gold is protected! Evidently it cannot be paid in gold, nor is it permissible to sell the metal on a free market. What a chance for a Get-Rich-Quick Wallingford if he could sell gold to jewelers for \$25 an ounce and get his pay in gold notes!

Why cannot we recognize the fundamental reason before it is too late and disaster ensues? Commodity prices are too high for safety not only to gold production, but to the whole industrial fabric of our nation. They must come down before they pull the entire superstructure upon our heads.

#### Inscrutable in the Ultimate

THE Administrative Chairman of the Honorary Advisory Council for Scientific and Industrial Research of Canada is publishing in installments a report of the Council's activities. The initial number is before us and we are informed that it is from the pen of Professor A. B. Macallum, the administrative chairman, and that it reflects more particularly his own views than those of his associates. In other words, that he is solely responsible for the opinions expressed. A large number of questionnaires have been sent to manufacturers and others and the returns, we learn, are in process of tabulation.

The value of such a body may be almost infinitely great, provided it undertakes its work with vigor, intelligence and understanding. On the other hand, unless it is exceedingly practical in coupling its efforts with measures relating to the general welfare, it is likely to lose public support, which is always a misfortune. Unnecessary duplication is another subject to be avoided, for research is research no matter where it is accomplished. One of the gravest errors made by the Germans was to cherish the belief that only they could practice applied chemistry. It was an expensive error.

Professor Macallum calls urgently and wisely for a great Institute of Research, and along with it he demands a Canadian Bureau of Standards. Now there is an excellent Bureau of Standards in Washington, the British standards are well organized and controlled in England and the two work together in harmony, but we have no desire to discourage the establishment of another bureau in the Dominion. If, however, they were to institute the metric system and were to co-operate with the French Bureau, some of us would wish them God-speed while others, both in the United States and Canada, might become addicted to tooth-nashing, for to some minds the metric system is like a red rag to a bull. But there is no intimation of co-operation with France in the report.

Elsewhere Dr. Macallum expresses an opinion that seems to us to be pointed straight in the wrong direction. He says of Canadian industrial establishments that many of them are not in a position to undertake research on a large enough scale to insure results, which is perfectly true, in Canada and everywhere else. He says also that they can enroll themselves in American associations formed for the purpose of solving their problems by research and that some of them have already done so. Also true. He even says that such co-operation *may* be unobjectionable and that there are no international boundaries in science.

It is what follows that pains us. "There are reasons," says he, "why this co-operation cannot be erected into an international system. Some of these concern a cast of psychology inscrutable in the ultimate, if you will, but nevertheless potent in directing a policy on this question. Our people could not ultimately be brought to approve of any proposal, however luring it might appear to them, if also its acceptance involved an effacement of the pride and independence that nationality essentially predicates."

That sentiment appeals to us as rank poison. German propagandists have long been sowing the seed of just such ideas. If honest men of Canada and the United States engage in research for the general welfare, we are simple-minded enough to believe that they can be trusted to proceed without "ultimate" designs upon the well-being or estate or patriotism of their associates. The chicanery he refers to is the kind of chicanery we are fighting to stop. It is intelligent rather than slick or smart or sharp to engage in industrial research. The only safe way to play the industrial game is with the cards on the table. In the "ultimate" many citizens of the United States may move to Canada and *vice versa* for industrial purposes, and even that is no great tragedy. Both countries can stand it; both have resources enough and to spare without setting up a cry over it. We live side by side, we are neighbors, we

are in the same fight for the same good cause and we cannot see the hazard that apparently is the basis of Dr. Macallum's suspicion. We sincerely hope that Canadian organizations for research and study will continue to welcome Americans as members and that our neighbors in applied science will continue to affiliate with such establishments on this side of the border. Let us put no barriers in the way of industrial research. We regret that Dr. Macallum has taken the attitude displayed in his official report.

### The Development of Water Softening

IN THE eventful years around 1770, when BURKE was pleading the cause of the colonies before the English parliament and predicting the wonderful future growth of these vast territories on the far shores of the Atlantic, WATT, the inventor of the steam engine, initiated the means for bringing BURKE's forecasts true, and LAVOISIER, the chemist, likewise gave the science of materials an impetus essential to the progress of the subsequent developments in engineering.

One of the most interesting features of the philosophy of the ancients was the theory that earth was formed from water. It was thus that they accounted for the islands and land apart from the seas, and there could be no dispute about it, because earth residues always accompanied the distillation of water. LAVOISIER, in his paper before the Académie des Sciences<sup>1</sup> in 1770, "On the Nature of Water and on the Experiments Adduced in Proof of the Possibility of Its Change into Earth," not only put an end to the water part of the time honored Fire-Water-Air theories of matter, but put the quantitative chemical science as instituted by JOSEPH BLACK and HENRY CAVENDISH on a firm basis in Paris, the capital of science at that time. Professor BLACK's researches on "fixed air" (CO<sub>2</sub>), burnt lime and the production of caustic potash form the premier study on quantitative chemical work. In subsequent years when boiler scale became important enough to command the attention of scientists, it was Professor CLARK of Aberdeen who profited from the work of BLACK and LAVOISIER and patented (1840) the softening of carbonated hard waters by neutralization with burnt lime. He thus started the cure of the trouble by the removal of the cause. In the eighty years of the Clark process, many improvements in both machinery and process have been made, which are so well known that they need not be described here.

Among the articles in this issue, considerable space has been allotted to the "Chemical Control of Water Softeners." The importance of water treatment is so fundamental to the needs of mankind that it has almost established a separate branch of engineering, located somewhere between chemical, civil and mechanical engineering. Recognizing that water treatment operations are not always under the control of men highly trained in stoichiometry and that softening machinery is often not installed, where needed, because it is considered too difficult to operate in small isolated operations, we are offering Mr. CLARK's paper in the hope that it will answer the requirements better than any of the prior literature on the subject.

## Readers' Views and Comments

### Consumption and Conservation of Tin

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—The Bureau has noted your anonymous article under the above title on page 175 of the August 15 issue of CHEMICAL & METALLURGICAL ENGINEERING. Since the main part of this article follows an extract from a report of the War Industries Board, and from the wording of that extract it might appear that the comment on tin-base bearing metals and solders originated from the Bureau of Standards, we wish you would call your readers' attention to the fact that such is not the case. There are statements in the article to which we cannot agree and which might defeat the Bureau's efforts on tin conservation.

The Bureau of Standards has developed solder composed of 80 per cent lead, 10 per cent tin and 10 per cent cadmium which is being used as a successful substitute for ordinary solders. It has been tried in many industrial applications and has been found very satisfactory.

S. W. STRATTON.

Bureau of Standards,  
Washington, D. C.

\* \* \*

The purpose of the article referred to was to indorse the movement for the conservation of tin and it would be unfortunate if it should in any way defeat the Bureau's efforts in that direction. Our statement to the effect that "metals such as cadmium have been tried as substitutes but are not of practical economic use" was based on the fact that cadmium costs per volume over three times as much as tin, oxidizes slightly above its melting point and does not give as strong a joint as regular solder. We are gratified to learn, however, that the Bureau of Standards has developed a satisfactory solder which should find wide use in view of the necessity of conserving tin. It should be needless to add that it is and has been at all times our desire to co-operate with the Bureau in its excellent work.

In a communication received subsequent to that published above, the Director of the Bureau states that while the relative cost of cadmium is greater than that of tin, only 10 per cent of cadmium is used in the substitute solder so that the entire metal cost of the cadmium-tin-lead solder is less than 35 cents per pound.—EDITOR.

### The Cotton Oil Industry in the War

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—In reading your very interesting account of the Cleveland meeting I noticed on page 548, Vol. 19, No. 7, a mis-statement in regard to the amount of oil which must be cleaned out of a ton of cotton seed. What I said was that it used to be considered good practice to get from 35 to 40 lb. of linters per ton of seed but the mills are now expected to obtain 145 lb. The price fixed on cotton seed varies by zones, according to the average amount of oil contained in the seed for each zone.

### Effect of Oxygen on the Precipitation of Metals from Cyanide Solutions

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—The abstract on page 283 of your issue of Sept. 15th of the important paper by Mr. T. B. Crowe on the above subject has been read with much interest. While admiring Mr. Crowe's ingenuity in bringing about so great a saving in the cost of cyaniding by the simple expedient of removing the dissolved air before precipitation by zinc, the writer cannot agree with Mr. Crowe's views in regard to the mechanism of the process.

In opposition to his view that precipitation of gold is brought about by hydrogen which has been displaced by zinc, and that the removal of dissolved air is beneficial because it prevents oxidation and loss of this reducing agent, the writer considers that the gold is directly displaced from solution by zinc, just as the same metal displaces copper from a solution of copper sulphate. The dissolving of zinc in a solution of pure sodium cyanide is a case of the displacement of one element by another, and differs from the dissolving of zinc in copper sulphate only in that hydrogen is displaced instead of copper.

It is this difference in the material displaced from solution that makes oxygen a necessity for the rapid dissolving of zinc or other metals by cyanide solutions, while the presence or absence of oxygen has no marked effect on the rate of dissolving of zinc in a solution of copper sulphate. If a strip of zinc be placed in an excess of dilute sulphuric acid the metal begins to go into solution and hydrogen is displaced; because the potential of zinc, or its tendency to dissolve, is greater than the discharge potential of hydrogen on the same metal, i.e., the force required to precipitate hydrogen, this action continues until all zinc has disappeared. If, however, the zinc be amalgamated, it is no longer appreciably attacked by the acid, although after amalgamation the zinc shows practically the same potential as before; it is because the discharge potential of hydrogen on mercury is greater than the potential of zinc in sulphuric acid that there is no visible evolution of hydrogen on amalgamated zinc. The displacement of hydrogen undoubtedly begins, but the potential of the cathode in the voltaic cell constituted by the mercury and zinc is raised by the layer of accumulating hydrogen until it equals the potential of zinc. When this occurs, dissolving of the zinc must cease. If now an oxidizing agent be added to the acid, or air be blown in, the zinc will dissolve, for removal of the film of hydrogen by oxidation enables the zinc to displace a new quantity of hydrogen. In this way the dissolving of zinc will continue so long as the hydrogen which it displaces is continually removed.

In a solution of sodium cyanide ordinary zinc acts like amalgamated zinc in acids, i.e., the hydrogen which the zinc displaces when it dissolves must be removed from the surface of the metal in order that continuous solution of the zinc may occur. When zinc is immersed in a dilute cyanide solution containing gold,

two reactions occur side by side; first, some of the zinc is dissolved by the double cyanide of gold with precipitation of gold; second, a portion of the zinc dissolves in the sodium cyanide with the displacement of hydrogen. Only the first action is useful. Every gram of hydrogen that appears means that 32.5 grams of zinc has dissolved without precipitating any gold, and that the amount of cyanide with which this zinc has combined is also wasted. Fortunately this wasteful dissolving of zinc is strictly limited to the amount of oxygen or air available for oxidizing the polarizing film of hydrogen.

Besides causing a loss of zinc in the manner indicated, dissolved air lessens the efficiency of recovery by accelerating re-solution of the gold already precipitated, just as air aids the dissolving of metals in cyaniding ores. It is this two-fold action that makes dissolved air a factor to be reckoned with in the economics of gold recovery.

## Special Gold-Recovery Processes Practised by the Early Portuguese and Spaniards

To the Editor of Chemical & Metallurgical Engineering

SIR:—When I had the pleasure of reading your number of METALLURGICAL & CHEMICAL ENGINEERING of June 1, 1918, I came across a very interesting letter, page 565, entitled "Special Gold-Recovery Processes Practised by the Early Portuguese and Spaniards," and I was the more interested in it as I have a personal experience of over nine years in gold mining in the State of Minas (Brazil), and I can therefore assure you that the facts related by Mr. Kirby Thomas are quite correct, and that this process is still being used now-a-days not only by the natives, but also by the most up-to-date gold mines in that country.

There is not the slightest doubt that it saves a fair amount of gold which would be lost by flotation.

It was specially used by the mining companies I was working with to facilitate the final obtention of the free gold in the *batea*. This primitive instrument (of African origin, if I am not mistaken and therefore probably invented by the early Egyptians) is nevertheless very efficient, and it is regrettable that its use is not more general outside of Brazil.

The plants yielding the sap which is employed to precipitate the floating gold are very numerous, but nearly all belong to the *solanea*, and the juices of this species are always slightly alkaline. Practically, however, only the sap of the plant called *jurubeba* is used by the natives—this mainly on account of its large leaves, which facilitate the obtention of a fair amount of sap without having too much trouble in gathering the primitive material needed. These leaves are roughly crushed by hand in a mortar and the whole pulp together with a small amount of water is put in a cloth and wrung to press out the liquid, which can then be used directly to precipitate any floating gold.

To do this, part of the water on top of the very rich sand contained in the bottom of the *batea* is drained off till the concentrates are uncovered. Some small particles of gold being thus allowed to dry would naturally float if more pure water was added to continue concentration. To obviate this the operator scoops up in his hand an amount of the *jurubeba* juice kept in a

special vessel, and sprinkles it very vigorously over the concentrates contained in the *batea*; and then adding the necessary amount of *jurubeba* juice, finishes the cleaning of the gold by skillful action of the *batea* without losing any gold by flotation on account of the vegetable liquid used.

I may add that the chemist in charge of the reduction department of that mine devised a strake concentrator in which the sap of the *jurubeba* was used instead of water to further concentrate the sands from the stamp strake, the solution being kept in circulation by a small centrifugal pump, it being naturally filtered after leaving the canvas-covered strakes and before being sucked up again by the centrifugal pump.

Personally I cannot give a very definite explanation of the action of the *jurubeba* juices, but I believe the action is just a cleansing process.

For instance, in the case of the floating needle which will not float if it has been cleansed or washed thoroughly with soap or sand-papered so that no particle of grease remains, it is sufficient to pass the needle through the fingers, or better still through the hair to restore its floating properties, showing very clearly that it is only necessary to have an infinitesimal film of greasy matter which naturally does not allow the water to wet the needle, and thus forms the depression on the surface of the water which supports the needle. And further I may note again that if you use instead of water a very slightly alkaline solution, the needle will not float, this being sufficient to neutralize the grease.

Now for this reason I think that the action of the *jurubeba* juice is very similar to this, because you must remember that the stamping process, as well as the friction in the *batea*, tends to polish the gold flakes, and they are therefore with difficulty wet by common water, but easily by the *jurubeba* juice, it being as aforesaid slightly alkaline.

Moreover the Portuguese when treating refractory ores used to slime the concentrate by grinding it under two flat stones, which form a small arastra, a process they used to call burnishing, showing you well that the small flakes of gold enclosed were polished.

Resuming I may say that this action of the vegetable sap of the Brazilian plants has quite a contrary effect to the one in the flotation process, as instead of trying to make the mineral particles float they try to make them sink, but the phenomena are explanatory of each other, as in the flotation process you try either to grease the mineral particles by the use of a small proportion of oil or create a gaseous film around these particles by acids which react on the concentrates, this gaseous film not allowing the mineral particles to be wet, just as the oil did it in the previous case, although in the latter case the gaseous film clinging to the mineral particles reduces at the same time their specific gravity.

In closing it may be interesting to note as an illustration of the skill acquired in working the *batea* that I tried an experiment with one of the women who was particularly clever in its use at the mine. To ten pounds of straight sand (the amount held in the *batea* ordinarily) I added 0.10 grams of fine assay gold which the woman then washed by the above method, and at the last she returned to me from the precipitate at the bottom of the *batea* 0.09 grams.

E. JORDAN.

240 Quebec Ave.,  
West Toronto, Canada.

ever, the impression is abroad that molybdenum alloys are more brittle than the corresponding tungsten equivalents, and are very tender under heat treatment. Thus the ordinary class of labor and equipment in the hardening room will give non-uniform results, which of course is fatal to its use in high-speed tools or modern ordnance.

## Built-in Laboratory Retort

By F. E. COOMBS

THE field of research in dry distillation is daily widening and increasing in importance. So far, there has been nothing offered in the way of experimental apparatus, either for operation on a small laboratory scale, or for commercial testing with large quantities. This article is descriptive of a still which has been in actual service found very easy to handle and entirely practicable, allowing the collection of gases as well as condensibles, and the isolation of all of the carbonized residues for exact weighing. It is especially valuable for finely divided materials, and for all high-temperature sublimations of non-corrosives.

In the accompanying drawings dimensions are not shown, as the scale will be sufficient guide. It is also to be noted that the header and cover-plate of the retort proper will be made of a suitable width to give a flange of about three inches, inclusive of the recess for the metallic seal, and that a clearance of about one-quarter inch should be allowed for around the tube openings, to give easy handling of the sheet metal containers.

The apparatus as scaled in the assembly sketch of the retort carried, in its four tubes, about fifteen pounds total of rather light powdered material, and the 4-in. diameter permitted complete carbonization in about thirty-five minutes.

The essential parts comprise two castings, of which

VERTICAL AND HORIZONTAL SECTION OF THE RETORT FURNACE

one is a chambered header with four threaded holes for the capped pipe nipples, and at its upper end a flange and a deep, narrow recess, to be filled with lead, or any alloy of convenient melting point, and further provided with a boss tapped for the outlet pipe, which pipe should be not less than 1½ in. in size. Upon the flange of the header casting rests a cover member, tapped for a strong ring bolt and having a continuous web, vertical to the flange, which fits very loosely into the recess of the header, and should seal therein in the fused alloy to a depth of about 2½ in. at the least.

Eight sheet-iron carrier cylinders are made which

fit easily into the capped pipes, without binding, and a perforated ear on each gives means for attaching an iron hook. With these containers the finished charge can be taken out and the newly filled set inserted in less than two minutes from opening the furnace to closing it again with a fresh charge.

The bottoms of the containers can be permanently closed; but in apprehension of trouble in cleaning out char, the sets actually made were merely flanged over inwardly at the bottoms, and loose round caps of sheet

CROSS-SECTION OF RETORT SHOWING HEAD, COVER AND CONTAINERS

metal used for closing. This was absolutely satisfactory, and no leakage occurred in filling or retorting.

The retort should be set in a brick furnace of proper form, which may be like the one shown and used, but in any case must have a deflecting wall, or plate, for securing a back-and-forth passage of the gases, so that the top will be heated as well as the bottom.

Over the top of the furnace is a pulley and rope, with an iron hook to fit the ring in the furnace top plate and the one in the retort cover-plate. The same rod may be used for removing the containers, but it will be found better to use a separate hook-rod for these, so that they may be swung freely to the closed can be used for preventing the combustion of the red hot coke of the discharge.

The exit pipe, or gooseneck, will project through one end of the furnace wall for connection to condenser.

The empty retort and cover are heated first, and the lead permitted to melt in the recess. When hot enough not to "freeze," the prepared containers are rapidly dropped into place, and the cover plate and furnace cover laid on. Distillation starts almost at once, but not too rapidly, as the capped pipe nipples will have just lost redness by the time the new charge is set in and the cover is on. Header free space is large enough to give a dust chamber, and sudden expansions or excessive gas evolutions may lift the cover but will not damage the apparatus. All or any less number of the carriers may be inserted, according to the freedom of evolution, and the retort is free of the furnace wall.

While the right to patent protection is reserved on large commercial forms of this design, the use of a four-chambered apparatus of 100 lb. capacity, or under, is open to public use.

Floriston, Cal.

## Symposium on the Conservation of Tin

A Discussion of the Tin Alloys—Bearing Metals, Solders, Bronzes and Substitutes—Conservative Spirit Displayed—Considerable Data Being Compiled by the Bureau of Standards on the Use of Cadmium Substitutes

AT THE Milwaukee meeting of the Institute of Metals Division of the American Institute of Mining Engineers held Wednesday morning, Oct. 9, several most prominent metallurgists read papers connected with our present tin situation. MR. GEORGE C. STONE called the meeting to order. MR. W. W. COWAN read DR. G. W. THOMPSON's paper in which he endorsed the increased use of lead in solder and bearing metal alloys.

### THE COPPER-BASE BEARING METALS

MR. G. H. CLAMER gave an excellent review of the use of lead in copper-base bearing metals as follows: In the early days, copper-tin alloys were almost universally used, the idea then being prevalent, and is still held by many, that a bearing to resist wear must be hard, and the harder the better. The favorite bronze bearing contained 90 per cent copper and ten per cent tin; frequently, in service which was considered severe, even higher proportions of tin were used. Such hard alloys have great resistance to compression, but as a rule they had a very wide factor of safety in this respect. Such bearings, because of their inability to adjust their surfaces to slight irregularities in the journal, or to foreign bodies, immediately begin to cut, and heating results. With a slight rise in temperature, the film of lubricant becomes thinner, and further cutting follows, if not actual gripment of the bearing with the journal.

Many years ago Dick, of England, appreciating the advantage to be derived from a slight plasticity in a bearing, added some lead to the then standard bearing metal, not substituting lead for tin but reducing the copper, and produced the alloy, which has long held favor as a bearing metal, copper 80, tin 10, lead 10 per cent. Dick's alloy also contained some phosphorus, but the main point is that this was the first step toward the production of bronze alloys having a plastic nature. Lead does not unite to form an alloy with copper, but remains mechanically mixed, so that structure of the alloy is that of a hard matrix with the soft metal imbedded therein.

It was not until several years later that tests were conducted on the Pennsylvania Railroad, under the direction of Dr. C. B. Dudley, who investigated the copper-tin-lead series within certain limits of the 80-10-10 alloy; he studied, not only the alloys containing lead above 10 per cent in which copper was replaced by lead, but also in which tin was replaced by lead. His conclusions, which have since become firmly established, are: (1) The rate of wear diminishes with increase of lead in the alloy. (2) The rate of wear diminishes with decrease of tin in the alloy. Fortunately, the alloy containing least tin and highest lead exhibits least tendency in service to give trouble from heating.

Notwithstanding the decided merit of copper-tin

bearings containing lead, prejudice was strongly against them, simply because lead is a low-priced metal. It was even intimated that such alloys were frauds, should be considered such, and dealt with accordingly.

I have mentioned Dr. Dudley's discoveries because it was due to its findings that the Ajax Metal Co. instigated research work, now 20 years ago, which has led to the production of alloys still higher in lead and lower in tin than those which he was able to produce. He experienced foundry difficulties which apparently limited his maximum lead alloy to 77 copper, 8 tin, and 15 lead. This was called Experiment B alloy, and has since been widely known as "Ex. B metal."

Having found due regard to the raw materials used, and by following good foundry practice, we have been able to produce alloys carrying 5 per cent of tin and as much as 30 per cent of lead which would show no segregation of lead, even if cast into large bearings. By this I mean that such bearings will show no indication of metallic lead upon any surfaces. Lead being only mechanically held in the alloy, it is prevented from segregating by the quick setting of the matrix of copper and tin. As a certain interval must necessarily occur between the time when the metal enters the mold and the time when it solidifies, the lead always shows some tendency, owing to its high specific gravity, to liquefy toward the bottom of the casting. In bearings made of the proper raw materials, and correctly handled, the difference in the proportion of lead is not usually over a fraction of one per cent, or at most 2 or 3 per cent, the top and the bottom of a casting, even if this be a fairly large one, and made of the 30 per cent lead alloy.

I do not wish to repeat here data which I have given in previous papers<sup>1</sup> but I do wish to set forth the position which the high-lead and low-tin alloys developed by us have attained. When these alloys were first produced they were backed only by laboratory tests and by the predictions of Dr. Dudley that, if such alloys could be commercially produced, the law which he established would no doubt apply also to alloys higher in lead and lower in tin than those which he had developed. It is now possible for me to review 18 years' experience with the manufacture and service of such bearings. I must confess that in our enthusiasm over the valuable properties of these alloys, we were led at times to overstep the mark and place such bearings in service where the loads or the impacts were too great.

The first requisite of a bearing is that it shall be sufficiently hard to support its load or to resist the impacts to which it may be subjected, and the relation of tin to lead must be controlled by this requirement. We have sometimes made mistakes in recommending the copper

<sup>1</sup>Int. Franklin Inst. (July, 1903), 156, 195. Proc. Amer. Soc. Testing Materials (1907), 7302. Amer. Inst. Metals (1915), 9241.

65, tin 5, lead 30, alloy for certain mill bearings, but this did not have sufficient resistance to compression, and failed for that reason. When the copper 73, tin 7, lead 20 alloy was substituted the bearings exhibited no deformation and performed far better than the 80-10-10 alloy previously used. We have also noted the failure of the 73-7-20 alloy on rod bearings of very heavy locomotives. Locomotive rod bearings are subjected to severe impacts and it is necessary therefore to use an alloy of fairly high compressive strength. Although the above alloy performs satisfactorily on light locomotives, on the rod bearings of heavy locomotives it is necessary to use either the 80-10-10 alloy or the same alloy to which has been added approximately 1 per cent of phosphorus. The size of these bearings, and hence their bearing surface, is narrowly limited by necessities of construction; otherwise these harder alloys would not be essential for this purpose. Phosphorus greatly increases the compressive strength of such an alloy, and is for this reason a possible factor for conserving tin. At the present prices of tin and phosphorus there is little choice; an alloy with 8 per cent of tin and 1 per cent of phosphorus will have compressive strength approximately equivalent to the alloy having 10 per cent tin. Experience, thus, has demonstrated that alloys containing as little as 5 or even 4 per cent tin and as high as 30 per cent lead, can be used in railroad service for the densest traffic. They have become the standard of the United States Railroad Administration for car-journal bearings called for under their Specifications R-71 Grade A. Such an alloy is also included in the specifications covering locomotive bearings designated as Specification R-72, Soft Bronze.

In my judgment, the specifications of the Railroad Administration covering locomotive bearing-metals are very satisfactory, except that the use of soft bronze should be extended to cover driving brasses, and engine and trailer-truck bearings. Before the Railroads of the United States came under Government control, copper alloys with low-tin and high lead contents had become the standard specifications of several of the large car companies, and were very extensively used on the largest railroad systems. Outside of the railroad field they had also been widely recognized and used. The advantage of using the smallest possible amount of tin consistent with the load requirements is now so well understood that there is but little opportunity for an important conservation of tin in this field.

Let us next consider the possibilities of substituting some other metal for a part or all of the tin in a copper-tin-lead alloy, or of substituting alloys of an entirely different type.

The first metal that presents itself as a substitute for tin is antimony. Antimony combines readily with copper and with lead, and has the property of adding hardness. Unfortunately, however, the hardening effect of antimony is obtained with the sacrifice of ductility. We have found it possible to make alloys carrying as high as 30 per cent of lead with 3 per cent of tin and 2 per cent of antimony. We have also made alloys of 65 copper, 30 lead, 2 tin, and 3 antimony, and have also replaced the 5 per cent of tin in this alloy entirely with antimony. Car bearings 4 1/2 x 8 in. size made from the same pattern and subjected to a breaking stress applied longitudinally at the middle of the back of the bearing

and throughout its entire length, broke at the following average loads: with 2 per cent antimony substitution, 60,000 lb.; with 3 per cent substitution, 62,000 lb.; with total substitution, 52,000 lb.: as compared with a breaking load of 67,000 lb. for the alloy of copper 65, tin 5, lead 30. The castings produced with each of the three above-mentioned alloys are not so satisfactory as those made with the straight tin alloys, being more or less rough, and showing slight globules of lead on the surface. It has been found that a certain amount of nickel can be used for replacing tin with very satisfactory results. The castings produced when zinc is substituted for a certain amount of tin are decidedly unsatisfactory. The substitution of aluminum for tin is entirely impractical, and such castings are worthless. This does not, however, exhaust all the possibilities of substituting other metals for tin in the copper-tin-lead alloys, but it is my opinion that the substitution of any other metals, in those alloys, can be made only by sacrificing the quality of the alloy.

The possibility of substituting alloys of an entirely different type presents an attractive field for research. The copper-tin-lead alloy has attained its position as the most desirable bronze bearing alloy, but this does not mean that some other alloy may not be found which may give equally good or better results. In the search for such a substitute alloy it should be borne in mind that a bearing metal should possess the following properties:

1. It should be sufficiently rigid to support the load or resist the impact, but yet not so brittle that it will easily crack.
2. It should have as great a yielding or plastic nature as is consistent with its ability to support the load or resist the impact without deformation of the bearing as a whole.
3. The ideal structure combines a hard matrix to support the load and a softer metal or alloy contained within such matrix, to permit the bearing surface to adjust itself to irregularities of surface.
4. It should be easy to handle in the foundry and machine shop.
5. It should be capable of being remelted without deterioration.
6. For use in babbitt-lined bearings, it should be capable of being tinned, so that the babbitt can be applied thereto.
7. It should have good heat conductivity in order to dissipate the heat generated by friction.

#### PENNSYLVANIA RAILROAD ANTI-FRICTION AND BELL METALS

Mr. H. M. WARING gave an interesting account of the approximate composition of the non-ferrous alloys in general use on the Pennsylvania Railroad as follows:

|                                   | Copper | Tin    | Lead  | Phos. | Antimony | Zinc |
|-----------------------------------|--------|--------|-------|-------|----------|------|
| Phosphor bronze, spec. 32-c       | 79 70  | 10 00  | 9 50  | 0 80  |          |      |
| Ex. B bronze spec. 141            | 76 75  | 8 00   | 15 00 | 0 25  |          |      |
| Special high lead bronze spec. 59 | 70 00  | 5 00   | 25 00 |       |          |      |
| Lining metal spec. 57             |        |        | 87 00 |       | 13 00    |      |
| Dandelion metal                   |        | 10 00  | 72 00 |       | 18 00    |      |
| Bell metal                        | 83 1/2 | 16 1/2 |       |       |          |      |
| Babbitt, machine                  | 3 70   | 88 00  |       |       | 7 40     |      |
| Babbitt for all bearings          | 1 00   | 50 00  | 38 50 |       | 10 50    |      |

Phosphor bronze is used principally for rod bushings, main-rod brasses, and crosshead shoes.

Ex. B bronze is used to a small extent for backs of car and coach bearings but the majority of these are now made of the car-journal bronze, which contains, on the average, about 5 per cent tin.

Car-journal bronze is used for making car and coach bearing backs at the Altoona brass foundry, by melt-

ing down old backs after removing the linings and making the necessary addition of new metal to bring the composition within the limits containing not less than 71 per cent copper, 4 per cent tin, 13 per cent lead and more than 0.20 per cent phosphorus and 3 per cent zinc. No new tin is added in making this alloy.

Special high-lead bronze is used principally for locomotive driving-box shells, which are not lined.

The lead-base lining for car journal bearings was formerly made up in our foundry from lining metal melted off from old bearings and brought up to specification requirements by the addition of such new metal as might be necessary. Some tin was unavoidably introduced from the old bearings, but the amount allowed in the metal was limited to 2 per cent. Lately we have been using this old lining metal in the preparation of the lead-base dandelion metal babbitt, thus making use of the contained tin in order to reduce the amount of new tin which it was necessary to add to this metal. The journal-lining metal is then made from lead and antimony without the addition of any tin.

Lead-base dandelion metal babbitt, containing about 10 per cent tin, is used for lining cross-head shoes and also for lining engine truck and trailer bearings, as well as for hub liners, in place of phosphor bronze, on freight locomotives. This metal has replaced a large amount of tin and tin-base babbitt formerly used.

Bell metal is used exclusively for making locomotive bells, and during 1917 about 42,800 lb. of castings were made, involving the use of a little over 7000 lb. of tin.

Tin-base babbitt metal (88.9 tin, 3.7 copper, 7.4 antimony) is used for a number of miscellaneous purposes in the shops, but its use has been greatly restricted and every effort is being made to do away with it where possible, and to substitute a lead-base babbitt or a babbitt with 50 per cent tin.

The amount of solder having the composition 50 lead, 50 tin, used by the Pennsylvania Lines East, during 1917, was approximately 100,000 lb. but there is reason to believe that a large portion of this can be replaced by a 60-lead, 40-tin solder with satisfactory results, and instructions have been issued to this effect.

In regard to the quantity of new tin used, it is not possible to give the amount except approximately, and from calculations based on the 1917 consumption of bearing metals by the Pennsylvania Lines East only, it is estimated that about 770,000 lb. of new tin were required in a total of about 21,380,000 lb. of all kinds of bearing metals turned out by the foundry or purchased in the market.

No change has been made in the specifications for bearing metals for some years, as the metals used have been satisfactory. A large proportion of the bearing metals are made up from old material re-melted and brought to standard composition by some addition of new metal, and every effort is being made to utilize old material to the best advantage and reduce the amount of new metal of all kinds purchased. For a number of years no tin has been used in the lining metal of either passenger or freight car journal-bearings, except such small amounts as come in from re-melting old linings. No change has been made in phosphor bronze used for rod bushings, as we should expect some trouble from bushings pounding out of shape if a phosphor bronze

were used which contained less tin or more lead than the present specifications call for. In this, as well as in the case of all other bearing metals, we expect to use our utmost endeavors to economize and to substitute for tin wherever possible.

#### SOLDER, ITS USE AND ABUSE

MR. MILTON L. LISSBERGER gave an excellent account of the properties of lead and tin alloys and the procedure of manufacturing commercial solders as follows:

Solder is a mechanical mixture of tin and lead. This is susceptible of a very quick and simple demonstration.

A bar of solder passed through a buffing machine even of a grade as low as 30% tin and 70% lead will show a surface practically identical with a bar of second quality or reclaimed tin.

The buffings when subject to a chemical analysis will show almost pure lead.

Now then, let us examine the reasons of this. Under the very best practice solder is made by first melting down the virgin pig lead. When the lead is absolutely liquefied virgin pig tin is added and a small amount of flux, the flux being for the purpose of bringing to the surface the so-called liver of metal that may have remained in either the lead or tin through incomplete refining.

The entire material when completely liquid is then thoroughly stirred for some hours. This mixture is next cast into small pigs. Just before casting into pigs, and continuously while this operation is going on, the kettle of molten metal is producing what is commonly called dross, but which in a great measure is actually the oxide of lead and tin, and this should be carefully skimmed off.

After these pigs of metal have been completely cooled, they are taken to a smaller kettle, re-melted and cast into the desired shape for use, or if to be made into wires, ribbons, etc., are cast in slugs suitable for extrusion and rolling.

While this second operation is taking place the skimming of the so-called dross should be, if anything, much more carefully done than when it is being cast into pigs.

Hand mixing has been proven as the only absolutely reliable method for the production of the best quality of solder. This means quality irrespective of the percentages of lead and tin that enter into the solder.

This last statement is made in view of the fact that the best quality of solder does not at all times mean the solder that contains the highest percentage of tin. The best quality of solder, as far as the proportion of lead and tin contents are concerned, is that composition which best performs on the required piece of work.

At this time, it is well to consider what does take place in the mixing of the lead and tin, and why there is a necessity of stirring for such a long period of time.

As stated at the outset, lead and tin do not form an alloy; therefore, to get a mechanical mixture as near perfect as it is possible to do, it is necessary to stir for a long period so as to break up the tin and lead into as small particles as it is possible to do, and to have these particles of lead and tin intermix.

Experience has shown that to perform this operation to the highest degree possible takes between five and

six hours, and this is irrespective as to the quantity of material being mixed.

Further, the difference in time is inappreciable between a mixture high in tin and one low in tin running in a commercial way down from 60 per cent tin to 30 per cent tin.

When the solder is first cast into pigs, and all through the casting process, what takes place is that the tin solidifies in the form of a skeletal mass. In the interstices of this skeleton rest the small globules of lead.

It is remarkable how many shapes these interstices take. The seeming explanation of these various shapes is the amount of other material present than tin and lead; hence very small, in fact it might be called chemical trace of foreign material present in the mixture causes a variation in shape.

To put this plainly, in a mixture made of chemically pure lead and chemically pure tin, the formation of the tin skeleton will differ from a material made where there is so much as one thousandth of one per cent of impurities.

As a further proof of the fact that solder is not an alloy of tin and lead: it would be found on examining the pigs first cast that there has been a segregation of the tin and lead equivalent to about one percent per perpendicular inch of height.

Taking a mixture of 50 per cent tin and 50 per cent lead, and casting it in a block six inches high, examination of scrapings made from the bottom of this block shows a composition of 47 per cent tin, 53 per cent lead. Borings made one inch from the bottom show 48 per cent tin, 52 per cent lead. Borings made two inches from the bottom show 49 per cent tin, 51 per cent lead. Borings made three inches from the bottom show 50 per cent tin, 50 per cent lead. Borings made four inches from the bottom show 51 per cent tin, 49 per cent lead. Borings made five inches from the bottom show 52 per cent tin, 48 per cent lead. Scrapings made from the top show 53 per cent tin, 47 per cent lead.

Now, you may mix as long as you want, but you cannot overcome this segregation provided the liquid solder is cast for the full six inches at one casting. Should, however, you cast one inch at a time into your mold, allowing it to cool before casting the next inch, you will find you are overcoming in a measure this segregation, but there is still a decided difference in the tin contents of the scrapings made from the bottom and the top of the pig.

Mr. Lissberger divided solder into two classes, that which is used strictly for soldering purposes, or the joining and holding together of pieces of metal, and second, that which is used primarily for filling, in which the joining is a secondary consideration.

He thought that the greatest abuse of solder is in the use of high tin mixtures for these filling metals. A mixture of 25 per cent tin and 75 per cent lead worked at the proper heat and with proper fluxing, he declared to be high enough for any filling purpose. This has been demonstrated in the practice of the oil canners, particularly the Standard Oil Co. The best means of conserving solder in can making, it was suggested, is to deepen all baths whether on line machinery or for hand dipping. Overheating of the baths should be avoided and the top of all baths covered with a pro-

tecting material, as sal ammoniac, oil, charcoal or ash.

Mr. Lissberger lamented the great waste of tin in the failure of many plants to save their dross. He gave his opinion that a 46 parts tin, 54 parts lead and  $\frac{1}{2}$  part antimony makes the strongest solder, though for machine work, as low as 38 per cent tin has given satisfaction. Later during a discussion before the meeting, Mr. Lissberger spoke at length concerning the substitution of cadmium for tin in solder and was very emphatic in stating the defects of this type of solder, though he did not specifically denounce the new 80-10-10 solder.

#### THE TIN-PLATE INDUSTRY

MR. STONE read the following from the paper of Mr. M. D. BUCK: During the first 5 months of 1918, approximately 11,000,000 lb. per month of pig tin were consumed in the United States. Solder bearing metals, bronzes, etc., used about 5,500,000 lb.; collapsible tubes a little more than 250,000 lb.; tin-foil about 500,000 lb.; and the tin- and terne-plate industry somewhat less than 5,000,000 lb. In an effort to reduce this consumption and thus conserve our tin supplies, several methods of procedure suggest themselves:

1. Salvage. The most careful and systematic collection and re-use of tin and tin-bearing materials is economically important, in that we thus secure the maximum benefits from our available supplies.

2. Substitution of other materials for tin. While tin, on account of its low melting point, softness, malleability, non-toxicity etc., is peculiarly adapted for many uses, nevertheless it may seem desirable, during times of temporary stringency at least, to substitute for tin and for tin-bearing materials some other substances which may answer our purposes, though perhaps not possessing all of the desirable qualities of tin. It is conceivable that research in this connection may develop entirely satisfactory substitutes which may permanently replace tin for certain purposes.

3. Curtailment, for the time being, of certain lines of manufacture, not absolutely essential to the prosecution of the war.

Efforts along all of the above-mentioned lines are being made in practically all tin-consuming industries, and much progress has been made. In considering the details of tin conservation, it is my intention to confine myself to a brief discussion of this subject as related to the tin- and terne-plate industry.

Terne-plate is a mild-steel sheet coated with an alloy of tin and lead (approximately 25 per cent tin and 75 per cent lead). Its chief uses, in normal times, are for roofing, gasoline and oil tanks, and for stamping into various forms. Manufacturers of this material have almost entirely discontinued its manufacture, except to supply the urgent needs of the Government for war purposes.

It has been customary to use a small amount of tin with the spelter in the galvanizing pots in the manufacture of galvanized sheets. It has been found that, by a sacrifice of no other quality than appearance, this tin could be omitted, and the practice has been largely discontinued—entirely so in the concern with which the writer is connected.

Tin-plate consists of thinly rolled mild-steel sheets coated with pure tin, and its chief use is in the canned-

food industry. The Government has requested that the manufacturers of this product give absolute priority to orders covering material to be used for the manufacture of plate for cans to contain perishable foods. The manufacturer has, of course, complied with this request and the conditions of the markets have been such that almost the entire capacity of the country has been utilized for such material and for other direct and indirect Government needs.

Several grades of tin-plate are regularly manufactured, differing only in thickness of the tin coating. While for some few uses the heavier coated sheets are desirable and necessary, it is a fact that the most lightly coated sheets are entirely suitable for a very large percentage of these requirements. It is in this connection that the consumer can materially aid in the saving of tin during the present stringency, and also prevent a serious economic waste in normal times, by not specifying a heavier coated plate than his requirements justify.

For years it was believed by certain canners, manufacturers, and dealers in canned goods, that a heavy tin coating was necessary on food containers. This opinion was endorsed by food officials and chemists, and attempts have been made in Congress to regulate the weight of tin coating. Since the literature on the subject gave no definite information, a committee was formed several years ago, consisting of representatives of the American Sheet and Tin Plate, American Can, and the National Canners' Association two representatives of the Bureau of Chemistry, Department of Agriculture, also participated in the work. This committee prepared seven lots of tin-plate with the following average coatings, expressed in pounds of tin per base box (112 sheets, 14 by 20 in.).

|         |         |         |         |
|---------|---------|---------|---------|
| A ..... | 0.9 lb. | E ..... | 1.8 lb. |
| B ..... | 1.1 lb. | F ..... | 2.1 lb. |
| C ..... | 1.3 lb. | G ..... | 3.0 lb. |
| D ..... | 1.5 lb. |         |         |

Cans were made from these plates in the usual way, and various food products were packed under the supervision of the committee, in regular canning plants.

The cans and contents were inspected and analyzed from time to time, throughout a period of about 18 months after filling the cans. In this work more than 40,000 samples were analyzed chemically. I quote from the general conclusions of this committee as embodied in their report:

"The most significant fact established by this entire investigation is that, aside from the external appearance of the cans, none of the difficulties encountered in the twenty experimental packs of twelve representative foods in plain cans was taken care of or eliminated by heavy tin coatings. . . . The luster and the resistance to rusting increase somewhat with increased weights of coating. In other respects, with the exception of some instances in those classes of foods that have a tendency to perforate, the conclusion from this work is that the value of different weights of tin coating on food containers is for all practical purposes the same with average weights of from one to three pounds of tin per base box."

I bring this investigation to your attention to emphasize the needless waste attendant upon the use of tin plate with an unnecessarily heavy tin coating. With our

present knowledge, we are unable commercially to produce coatings as light as the lower weights used in this test. If, however, future research should develop means to this end the resultant product would meet all practical requirements, and a very considerable saving in pig tin would result.

#### THE BUREAU OF STANDARDS INVESTIGATIONS

DR. PAUL D. MERICA presented the paper by MESSRS. G. K. BURGESS and R. W. WOODWARD, from which the following are extracts:

"There is no question but that the tin content of nearly all bearing metals can be reduced to some extent, and in some cases actually eliminated without prejudice to the service rendered. So the problem is to determine what needs are the most exacting, or when a breakdown would cause the greatest damage and confine the use of high tin babbitts to these uses only. Thus the main bearings of airplane and military automobile engines, turbine shafts, etc., will probably have to continue to use high tin babbitt with a tin content of from 84 per cent to 91 per cent. A babbitt metal such as S. A. E. specification No. 24 containing 84 tin, 9 antimony and 7 copper appears to be as satisfactory in service as one such as genuine babbitt, 89 tin, 7½ antimony, 3½ copper, or that specified by the International Aircraft Standards Board, 91 tin, 4½ antimony and 4½ copper; but it should be pointed out that the latter two compositions are more fluid in the molten condition than the first named and consequently the lining can be made in a thinner shell with these babbitts and the total amount of tin consumed may therefore be less than if the S. A. E. No. 24 was used. However, if the design of the bearing is not altered to admit of the thinner shell, the lower composition babbitt should be used in general.

The following compositions are also recommended for use where a high grade of lining is required and when a genuine babbitt is often now used:

|           | No. 1    | No. 2 | No. 3 | No. 4 | No. 5 | No. 6 |
|-----------|----------|-------|-------|-------|-------|-------|
| Tin       | 65       | 62    | 8     | 5     | 10.0  | 21.3  |
| Antimony  |          |       | 8     | 7     | 12.5  |       |
| Copper    |          |       | 4     | 2     | 0.5   | 3.0   |
| Zinc      | 28 to 30 | 33    |       | 76    |       | 63.3  |
| Aluminium |          | 1     |       |       |       |       |
| Lead      |          |       | 80    | 10    | 77.0  | 12.0  |

Nos. 3 and 4 have been found to do the service required of tin base linings in machine tool bearings; No. 5 can be used on similar bearings where a greater strain is met. No. 6 is in use in Germany as a "best" babbitt to conserve both tin and copper.

For linings on railroad truck journals two compositions are in general use, one composed of 85 lead, 10 antimony, 5 tin, and the other of 87 lead and 13 antimony. The latter is restricted by some roads to freight service and the former used on passenger equipment. Many roads, however, use the 87 lead and 13 antimony on both classes of service and it seems that its use might be made more universal.

Another type of lining metal which deserves serious consideration is one composed almost entirely of lead with small additions of alkali or alkali earth metal. Certain of these have been given service tests at the Bureau of Standards and in many respects were found equal to or superior to genuine babbitt.

Following is a summary of the tests on the metal and

similar tests on genuine babbitt of composition 89 tin, 7½ antimony, 3½ copper:

## Genuine Babbitt

| Lead, lb. per cu. in. | R. P. M. | Total No. of Revolutions | Final Temp. °C | in 12" Temp. °C | Rise Temp. °C | Friction Weight 1 lb. Gram | Loss in Weight 0.023 | Remarks |

Bearing still good condition.

## STANDARD GRADES OF BABBITT METAL

At a meeting called by the Conservation Division of the War Industries Board on April 15, 1918, which was attended by manufacturers and users of bearing metals, the Bureau of Standards was requested after conference with technical representatives of the large manufacturers and users, to determine if four classes of babbitt metal could be adopted ranging in tin content as follows:

A—Genuine babbitt, 89 per cent tin.

B—Genuine babbitt, 40 to 50 per cent tin.

C—Genuine babbitt, 4 to 6½ per cent tin.

D—Genuine babbitt, no tin.

The bureau has gone over the situation with several of the representatives and the general opinion seems to be that it is impossible to limit some of the classes to a single composition, because of the fact that several compositions of nearly the same tin content are in general use for different purposes. Thus in the table below No. A1 is used in aircraft engines, No. A3 is used for automobile engines, No. A4 is found in bearings of electrical machinery. It was thought, however, that class B can be entirely dispensed with, as these intermediate tin content bearing metals are in no way as satisfactory as either a high lead or high tin base babbitt. In all cases where class B could be used, class C or class D will be found to serve the purpose equally as well. There are, however, some grades of babbitt containing about 65 per cent of tin which do not fall into either class A or class B, but which are often claimed by the manufacturers to equal the high tin babbitt in performance. If these claims can be substantiated this babbitt should be considered as falling into the category of class A and as being a substitute for alloys in that class.

It should not be presumed, because high tin babbitt of class A is included, that the bureau recommends the continuance of its use for many bearings in which it is now used. The lowest possible tin content alloy should always be used, and the bureau believes that it might be advisable to leave some central body issue license for the use of babbitt in class A in order to insure that no class A babbitt is being used where others are satisfactory.

Alloy D2 has been included in class D because this comprises babbitt metals containing no tin. It should be noted, though, that this alloy will be found satisfactory in many installations where class A has hitherto

been used and its inclusion in class D should not give the impression that it is a low grade babbitt.

The American Society for Testing Metals has drawn up specifications for twelve compositions of babbitt metals (B23-18T) which, however do not take into consideration the factor of tin conservation, but are formed for use in peace times. The present recommendations are for use in the existing situation, where the saving of all tin possible is of prime importance.

The recommended compositions for the various classes are given in the table below. These compositions have been selected so as to include existing specifications and usage of babbitt metals as far as possible. Much information has been secured from the questionnaire sent out by the bureau and from replies to the general letter issued by the War Industries Board on May 29, 1918.

| Class | No. | Tin Per Cent                 | Antimony, Per Cent                   | Lead, Per Cent | Copper, Per Cent | Iron, Max. | Arsenic, Max. |

Large quantities of phosphor bronze of the compositions 80 copper, 10 lead, and 10 tin are dioxided with phosphorus, are used in unlined bearings at fairly high speeds and pressures. The following compositions have been suggested as substitutes for phosphor bronze, although it is our opinion that trouble will sometimes be experienced with Nos. 8, 9 and 10, because of the high lead content, although they have about the same tin content as the others in the list.

## STRUCTURAL BRONZES

Passing now to the bronzes other than those for bearing purposes, we find that "Government Bronze" (Navy Specification, 46M6a, Gun Metal) or 88 copper, 10 tin, and 2 zinc, is used in large quantities and can also be modified to admit of a saving of tin without impairment of the physical properties sought. Experiments by the Bureau of Standards and others have shown that a composition of 88 copper, 8 tin, and 4 zinc, is equal to or superior to the ordinary Government bronze. Aluminium bronze of composition 90 aluminium, 10 copper, for example, can also be substituted for many uses of Government bronze as can also manganese bronze and naval brass. There have also been introduced several aluminium bronzes containing small amounts of iron, which can be either cast or wrought, and which are now being used by several former users of Government bronze.

Some manufacturers have raised an objection to using aluminium bronze because the scrap accumulating from this alloy, if it gets mixed with other metals, particularly value metals, would have a deleterious effect upon them. This is simply a problem in works management of properly sorting and routing scrap. We know of several large manufacturers who make aluminium bronze castings in the proximity of steam metal castings and who by taking the proper precautions have encountered no difficulties.

The following table gives some of the properties of the above mentioned alloys:

| Alloy                                                 | Tensile Strength<br>Lb.<br>Sq. In.           | Elastic Limit<br>Lb.<br>Sq. In. | Elongation<br>in 2 In.<br>Per<br>Cent. | Authority                                                                                                       |

#### CADMIUM AS TIN SUBSTITUTE IN SOLDER

Cadmium appears as a promising substitute for part of the tin in solders. The bureau has been developing such a solder, and laboratory test together with manufacturing experience so far point to a composition of 80 lead, 10 tin and 10 cadmium as being practical for many of the purposes for which solder is required. This solder has been tried in the manufacture of tin cans, on roofing materials, and for electrical joints with encouraging results in all cases. Before using it for food containers, however, it will be necessary to ascertain its toxic properties under various conditions. A test has also been made of it in the manufacture of automobile radiators with most satisfactory results.

The tensile strength of the cadmium solder is about the same as that of 40-60 solder, but the ductility is approximately twice that of the ordinary solders. The point of complete liquation is only slightly higher than that of the ordinary composition of solders, while the range of solidification is considerably greater. Table I gives some of the provisional data on these solders as compared to the tin-lead solders; the tensile properties given are the average of four determinations and even made on a Scott testing machine, the rate of separation being about twelve inches per minute.

Because of the preponderance of lead in the cadmium solder, the price of it is very reasonable; with the present market prices of the metals involved it is thought that the 80-10-10 solder can be sold at a profit at 35 cents a pound. It is also thought that plenty of cad-

mium can be produced as soon as the market of it is created as there are undoubtedly available American sources of cadmium which are not at present exploited.<sup>2</sup>

In meetings with manufacturers of materials containing tin it is always brought out that the Government is the worst offender, and that many Government

specifications often call for a lavish use of tin which is sometimes detrimental to the quality of the material manufactured. We believe, however, that many of these specifications are being revised in order to conserve tin, but that there is still room for further improvement. As a means of conserving the use of tin by the Government, we would suggest the advisability of creating a joint committee of technical representatives of the various departments to pass upon or revise all Government specifications containing tin. Such a committee could be in close co-operation with the manufacturers and would form a better means for the manufacturers to criticise the tin content of Government specifications than now exists in any of the departments.

#### OTHER TOPICS IN BRIEF

MR. J. L. JONES of the Westinghouse Electric & Manufacturing Co. stated that his company had found that a lead based babbitt of 78 per cent lead, 14 antimony and 8 tin was suitable for all types of electrical machinery. This alloy has a Brinnell hardness of 27 to 28, pours well and is tough and clean. Great care must be taken in its preparation to prevent segregation etc. Furthermore many babbitt linings are being made  $\frac{3}{16}$  inch in place of  $\frac{1}{8}$  inch. He described a special solder pot for melting babbitt metal which his company has found very advantageous, in that a complete separation of the accompanying oxides is obtained, making clean castings as well as economizing materials.

MR. W. M. CORSE of the Titanium Bronze Co. gave an excellent paper on aluminium bronze which pointed out the excellence of this type of alloy. This paper will be published separately in the near future.

MR. H. D. EGBERT of the Research Corporation pointed out the applicability of electric dust precipitation of the tin vapors at the sash weight foundry cupolas, where old tin cans, etc., are melted up. The development of this field promises a very important recovery, as there need not be a very great expenditure in cleaning off labels, etc., from the cans, which can be crushed, dried and smelted.

# Calculation of Extraction in Continuous Agitation

Derivation of a Mathematical Formula for Continuous Systems of Extraction in Hydrometallurgy and Industrial Chemistry — Examples of Application — Modifications for Non-Homogeneous Material and Where Complete Reaction is Required

BY ANDREW HAM AND HARRISON STREETER COE

**EDITOR'S NOTE.**—The accompanying article has for its basis a paper offered for publication by Mr. Andrew Ham on the mathematical relation between the efficiency of continuous and intermittent agitation.

The deductions seemed to be of unquestionable value, but the mode of presentation, which included the derivation of the formula by calculus, seemed somewhat too intricate. With Mr. Ham's approval we invited the co-operation of Mr. H. S. Coe, who confirmed the correctness of the premises and the computations. He has also presented the formula in a different manner, with Mr. Ham's tables modified to be directly applicable in designing continuous agitation plants and determining the losses to be expected therefrom. Mr. Coe further discusses various features not touched on by Mr. Ham and gives a method for making simple tests which will show the relation between continuous and intermittent agitation of ores containing difficultly treated fine sand.

For those desiring to follow the derivation of the formula, Mr. Ham's calculations are appended.

## INTRODUCTION

**I**N THE fields of hydrometallurgy and industrial chemistry, wherever chemical reactions are accelerated by mechanical agitation, the tendency, during recent years, has been to replace the primitive intermittent charge-agitation method by continuous agitation.

Economy of operation has been the principal incentive to this change; and where the nature of the reactions permit, it is generally conceded that continuous agitation has a tremendous advantage over the old method. No one, as far as we are aware, has thus far made public any exact analysis of what physically occurs in a continuous-agitation system, so that treatment by this method can be compared to that in an intermittent-agitation tank. A formula for doing this has been derived by Mr. Andrew Ham and is submitted and explained in Part I of this article.

The method presented for applying the formula differs from that offered by Mr. Ham, but otherwise Part I of this article is a presentation of his formula explained as simply as possible. It follows his own reasoning quite closely, eliminating the somewhat involved mathematical derivation, which is given at the end of the article.

In Part II Mr. Coe offers a discussion of the application of the formula and of some features which modify its use. Conclusions are drawn relative to the use of the formula.

## I. DERIVATION AND EXPLANATION OF FORMULA

In general, the difference between the operation of intermittent and continuous agitation may be stated as follows: Whereas in the former method the vessel in which a process takes place has to be filled (and

closed under special conditions where heat, pressure, etc., are required) and later emptied at the completion of the treatment, the continuous-agitation system provides a series of vessels (or sometimes only one) in which the material to be treated enters and leaves the system in an uninterrupted stream or at regular intervals. The essential difference in the treatment is that in continuous agitation new material is mixed with material which already has been subjected for some time to the process. Different parts of the material are thus in different stages of treatment, or of different "age," and the material passing out of the system comprises particles which have been subjected to agitation for different periods of time.

It is to determine this "detention" or treatment period which different percentages of the material have had on leaving a continuous-agitation system that the formula given hereafter has been derived.

To establish the formula, a small part of the material which enters a continuous-agitation system in a negligible interval of time is considered; and the proportion of this part remaining in the system after the lapse of any given interval of time is determined.

The small part is called  $a_0$ . The quantities  $v_1, v_2, v_3$ , etc., represent the fractions of  $a_0$  remaining in the first vessel, second vessel, third vessel, etc., of the system after an interval of time  $T$  rated from the entrance of  $a_0$  into the first vessel.

$V_1, V_2, V_3$ , etc., represent the fractions of  $a_0$  remaining in the first vessel, first two vessels, first three vessels, etc.; and if the total number of vessels in the continuous-agitation system be  $n$ ,  $V_n$  represents the fraction of  $a_0$  remaining in the whole system after time  $T$ ; i.e., the fraction of  $a_0$  which has been treated for time  $T$ .

It will be noted that  $V_1 = v_1$  (and where  $n = 1$ ,  $V_n = V_1 = v_1$ ),  $V_2 = v_1 + v_2$ ,  $V_3 = v_1 + v_2 + v_3$ , and  $V_n = v_1 + v_2 + v_3 + \dots + v_n$ . Since every portion of the entering material has the same experience in passing through the system, the numerical values of  $v_1, v_2, v_3$ , etc., and  $V_1, V_2, V_3$ , etc., apply to all of the material agitated. Thus, if  $T$  is 1 hour and  $v_1$  is 0.5 and  $v_2$  is 0.1,  $V_2$  will be 0.6 which means that 50 per cent of the material entering the continuous-agitation system receives 1 hour of agitation in the first vessel and 60 per cent receives 1 hour of agitation in the first two vessels. If the continuous-agitation system contains only two vessels,  $V_2$  will be  $V_n$ . The  $v_2$  or 10 per cent found in the second vessel is made up of particles which have received part of their treatment in the first and part in the second vessel, each with a total of 1 hour of agitation.

With all vessels of equal volume in the continuous agitation system the formula for  $v_1, v_2, v_3$  is  $v_1 =$

$$e^{-zT}, v_2 = \frac{zT}{1} e^{-zT}, v_3 = \frac{z^2 T^2}{2} e^{-zT}. \text{ The general formula is}$$

$$v_n = \frac{z^{n-1} T^{n-1}}{1.2.3 \dots (n-1)} e^{-zT}$$

where  $n$  is greater than 1. In this formula  $e = 2.71828$  (the natural base of logarithms),  $z$  depends on the size of the vessels and the rate of inflow of the substance

and is equal to  $\frac{\text{rate of inflow}}{\text{capacity of vessel}} = \frac{1}{\text{time to fill the vessel}}$

or  $\frac{R}{C}$  where  $R$  = rate of inflow and  $C$  = capacity of vessel.

Since  $V_n = v_1 + v_2 + v_3 + \dots + v_n$ , we have, by giving  $v_1, v_2, v_3$ , etc., their proper value, the general value for  $V_n$  which is,

$$V_n = e^{-zT} \left( 1zT + \frac{z^2 T^2}{2} + \dots + \frac{z^{n-1} T^{n-1}}{1.2.3 \dots (n-1)} \right).$$

Values of  $V_n$  from  $V_1$  to  $V_7$  are given in Table 1, for varying values of  $zT$  and will help to analyze the treatment received in continuous-agitation systems of from 1 to 7 tanks.

Mr. Coe has added column  $B$  to facilitate the use of the table.

In column  $zT$ ,  $z$  is assumed to be a constant for the problem considered, such that the inflowing material just fills one tank in the continuous-agitation system in the time required to treat it by intermittent agitation;  $zT$  therefore becomes  $\frac{\text{time agitated}}{\text{time required}}$ . This column

helps to compare directly the treatment in an intermittent-agitation tank with that in continuous-agitation systems comprising tanks of the same size as the intermittent-agitation tank; and as hereafter shown may be used indirectly in comparing treatment in an intermittent-agitation tank with continuous agitation systems made up of tanks of other sizes.

In column  $B$ ,  $T$  is taken as a constant for the problem considered;  $T$  being a given required period of agitation by intermittent agitation. In this case,  $RT$ , the quantity of material entering the continuous-agitation system in time  $T$ , equals the volume of an intermittent-agitation tank required to treat  $RT$  units of material in time  $T$ . The numerical values given in column  $B$  represent the ratio between the size of each tank in a continuous-agitation system and that of the required intermittent-agitation tank to treat the same quantity of material (assuming the latter to work without lost time, which is of course impossible).

#### EXAMPLES OF USE OF TABLE

If we consider a homogeneous substance to be treated we may compare the size of tanks in the continuous-agitation systems necessary to give required results, to that of an intermittent-agitation tank doing the same work.

*Example 1.* Let us say arbitrarily that 98 per cent of the material must be agitated for the full period of time required by intermittent agitation.

In column  $B$  of the table,  $T$  is assumed to be this full period, and we may note that

In a continuous-agitation system where  $V_1 = .98, B = 50.0$   
In a continuous-agitation system where  $V_2 = .98, B = 1.0$   
In a continuous-agitation system where  $V_7 = .98, B = 0.379$  (by interpolation)

In other words, to give full treatment to 98 per cent of the material by continuous agitation requires a continuous-agitation tank 50 times as large, a four-tank continuous-agitation system with each tank of the same volume, a seven-tank continuous-agitation system with each tank of 0.379 the volume of the required intermittent-agitation tank.

*Example 2.* Comparison of treatment in a three-tank continuous-agitation system with that in an intermittent-agitation tank of the same volume as each continuous-agitation tank and treating the same quantity as the continuous-agitation system. In column  $A$  of the table the fractions of the total treatment period are given and in column  $V$ , the fractions of the material receiving these fractions of the treatment period are shown.

Thus 0.999 remains in the continuous-agitation system for 0.2 full periods  
0.977 remains in the continuous-agitation system for 0.6 full periods  
0.920 remains in the continuous-agitation system for 1.0 full periods  
0.809 remains in the continuous-agitation system for 1.5 full periods

The fraction of the total soluble substance dissolved during the passage of the material through the continuous-agitation system is as follows:

Between 1.000 and 0.999 of total soluble by agitation between 0 and 0.2 full periods  
+ Between 0.999 and 0.977 of total soluble by agitation between 0.2 and 0.6 full periods  
+ Between 0.977 and 0.920 of total soluble by agitation between 0.6 and 1.0 full periods  
+ Between 0.920 and 0.809 of total soluble by agitation between 1.0 and 1.5 full periods

By taking the fractions of the agitation period closely together, a close estimate of the fraction of the total solubles dissolved may be reached.

*Example 3.* Comparison as in example 2 where the continuous-agitation tanks are not equal in volume to the intermittent-agitation tank required.

In this case multiply the numerical value given in column  $zT$  by the ratio,

$$\frac{\text{volume of tank in continuous agitation system}}{\text{volume of intermittent agitation tank}},$$

Thus if we are comparing a continuous-agitation system where the volume of each tank equals one-half the volume of the required intermittent-agitation tank the fraction of the treatment period given in column  $zT$  must be multiplied by one-half and the results for a three-tank continuous-agitation system would be

0.999 remaining in system for 0.1 full periods  
0.977 remaining in system for 0.3 full periods  
0.920 remaining in system for 0.5 full periods  
0.809 remaining in system for 0.75 full periods  
0.676 remaining in system for 1.00 full periods  
0.423 remaining in system for 1.50 full periods

The fraction of the total soluble substance dissolved during the treatment should be:

Between 1.00 and 0.999 of total soluble by agitation between 0 and 0.1 full periods  
+ Between 0.999 and 0.977 of total soluble by agitation between 0.1 and 0.3 full periods  
+ Between 0.977 and 0.920 of total soluble by agitation between 0.3 and 0.5 full periods  
+ Between 0.920 and 0.809 of total soluble by agitation between 0.5 and 0.75 full periods  
+ Between 0.809 and 0.676 of total soluble by agitation between 0.75 and 1.00 full periods  
+ Between 0.676 and 0.423 of total soluble by agitation between 1.00 and 1.50 full periods

The fractions of substance soluble during the fractional periods indicated are to be taken from extraction tests made by intermittent agitation.

## II. APPLICATIONS OF FORMULA

Mr. Ham's formula applies directly to designing continuous-agitation plants, using laboratory tests by intermittent agitation as a basis, provided the material to be agitated is homogeneous; i.e., uniform in size and weight of particles, and if the solvent is maintained at practically the initial strength throughout the treatment.

Where the solids to be agitated contain particles of varying size and weight the use of the formula may be changed due to the concentration of coarse material in the tanks of the continuous-agitation system.

In agitators where the contents are kept in violent motion, there is no chance for such concentration and the formula applies directly, since the material as a whole remains homogeneous. In another type of agitation, such as the Dorr, there is abundant opportunity for concentration of the heavier particles, since the material simply settles to the bottom of the tank to be collected and elevated (together with solution) to the surface by means of an air-lift and redistributed over the tank. When operation is started, the first tank acts therefore as a sand trap. The sand collected from the inflowing material increases until an equilibrium is reached; after which the sand in the material passing over to the second tank will be in the same proportion as in that entering the system.

If we assume that the soluble substance most slowly dissolved is in the sand, which is nearly always true, and that the sand in the tanks is concentrated to, let us say, four times its concentration in the inflow, then relative to the sand treatment each Dorr agitator in the system acts as a tank four times as large as would be indicated by its actual volume; except that the sands so concentrated are not continuously treated with the same solution but receive constantly a fresher solution which accompanies the slimy parts of the ore in its more rapid passage through the system. In other words the feed to the system is of one dilution but the agitation proper is effected on a denser pulp with the effect of constantly adding fresh solution.

Thus in example 3, the percentage of soluble substance dissolved would be raised to

+ Between 1.00 and 0.999 of total substance in sand soluble between 0.2 and 0.4 full periods  
+ Between 0.999 and 0.977 of total substance in sand soluble between 0.4 and 1.2 full periods  
+ Between 0.977 and 0.920 of total substance in sand soluble between 1.2 and 2.0 full periods.

With tanks each one-half the size of the intermittent-agitation tank required showing such complete treatment, it appears quite probable that the total volume in the continuous-agitation system might be equal to or less than that of the required intermittent-agitation tank and yet give better extraction than the latter. Results from practice confirm this view.

### MODIFICATION NECESSARY IN SPECIAL CASES

Another case where it seems necessary to modify the use of the formula is where a complete reaction is required in the system, the solution to be neutralized as well as the substance to be dissolved. The strength of solution in each tank may be computed from the table, provided the rate of reaction of solution of blended strengths on blended fresh and partly treated material is the same as when the relative fractions of the solution and material are agitated alone. It would appear that a

relation between these rates might be established by laboratory tests, and Mr. Ham's formula would then become useful for this case.

## CONCLUSIONS

From the foregoing explanation and the treatment features noted in Part II it is Mr. Coe's conclusion that Mr. Ham's formula is directly applicable in a limited number of instances but that its chief value lies in the fact that it gives a method to study the history of the material in passing through a continuous-agitation system.

When its use is modified to conform to conditions above noted it should be of distinct value in designing continuous-agitation plants. It also affords a starting point for estimating the relative merits of various continuous-agitation systems and for determining whether continuous agitation is suitable to the reaction under consideration.

## DERIVATION OF FORMULA BY ANDREW HAM

For general explanation see Part I of this article.

Let  $a_j =$  a small quantity of material entering the system during a negligible interval of time.

Let  $t$  = time, rated from the entrance of  $a_0$  into the system.

Let  $R$  = rate of flow of material into the system and from tank to tank.

Let  $c$  = capacity (volume) of each tank in the system.  
 Let  $a$  = the quantity of  $a_0$  remaining in tank No. 1  
 after time  $t$ .

Then  $\frac{a}{c}$  = quantity of  $a$ , in a unit volume of the contents of number 7 tank at any time.

—  $R_c^a$  = the rate at which  $a_o$  is leaving tank No. 1.

+  $\frac{da}{dt}$  = the rate at which  $a_o$  is leaving tank No. 1.

$$\therefore \frac{da}{dt} = -\frac{Ra}{c} \text{ or } \frac{1}{a} da = -\frac{R}{c} dt.$$

Let  $\frac{R}{c} = z$  (a constant for the problem considered)

$$\text{Then } \frac{1}{a} da = -z dt, \quad \int \frac{1}{a} da = \int -z dt$$

$$\log a = -zt + c \quad (c = \text{constant of integration})$$

$$a = e^{-zt+c} = (e^{-zt})(e^c)$$

Let  $t = 0$ ; then  $a = a_o$  and  $a_o = (1)(e^c)$

$\therefore a = a_o e^{-zt}$  or  $\frac{a}{a_o} = e^{-zt}$  (I). This is the fraction of  $a_o$  in tank No. 1 after any time  $T$ . Call this fraction  $v_1$ .

#### CONSIDERATION OF TANK No. 2

$\frac{da}{dt}$  = rate at which  $a_o$  leaves tank No. 1 at time  $t$ .

$$da = -a_o z e^{-zt} dt \quad (\text{from (I)}).$$

$-da$  = the quantity of  $a_o$  entering tank No. 2 during interval  $dt$  at time  $t$ .

$\frac{da}{-da}$  = the fraction of  $(-da)$  remaining in tank No. 2 after time  $t$ , rated from the entrance of  $(-da)$  at time  $t$ .

Hence, by comparison with (I):

$$\frac{da'}{(-da)} e^{-zt} = (a_o z e^{-zt} dt) e^{-zt}.$$

Let  $t + t_1 = T$ , a constant, the time for which the investigation is being made. Then  $t_1 = T - t$  and  $da' = a_o z e^{-zt} dt$ .

$a' = \int a_o z e^{-zt} dt = a_o z t e^{-zT} + c'$  ( $c' = 0$  = constant of integration).

$\therefore$  at time  $T$ ,  $a' = a_o z t e^{-zT}$  or  $\frac{a'}{a_o} = z T e^{-zT}$  (II). This is the fraction of  $a_o$  remaining in tank No. 2 after time  $T$  rated from the entrance of  $a_o$  into system. Call this fraction,  $v_2$ .

#### CONSIDERATION OF TANK No. 3

Here we have the condition of a continuous supply of  $a_o$  reaching tank No. 2 and also leaving it, whereas in No. 1  $a_o$  arrived all at once.

$-da$  enters No. 2 in interval  $dt$  and  $\frac{da'}{dt}$  (the rate of change in the quantity of  $a_o$  in No. 2 is made up of  $(\frac{da}{dt})$  and the rate of  $a_o$  passing to tank No. 3.

$$\text{Hence } \frac{da'}{dt} + \frac{(-da)}{dt} = (a_o z^2 t e^{-zt} - a_o z e^{-zt})$$

$= a_o z^2 t e^{-zt}$  is the rate at which  $a_o$  is entering No. 3 at time  $t$ .

$-(da' + da) = a_o z^2 t e^{-zt} dt$  = quantity of  $a_o$  entering No. 3 during  $dt$  at time  $t$ .

$\frac{da''}{-(da' + da)}$  = fraction of  $-(da' + da)$  remaining in No. 3 at time  $t$ , rated from entrance of  $-(da' + da)$ .

By comparison with (I):

$$\frac{da''}{-(da' + da)} e^{-zt_1} = (a_o z^2 t e^{-zt} dt) e^{-zt_1}.$$

Again let  $T = t + t_1$ ; then

$$da'' = a_o z^2 t e^{-zt} dt.$$

$$\int da'' = a'' = \int_{t=0}^{t=T} a_o z^2 t e^{-zt} dt = a_o \frac{z^2 T^2}{2} e^{-zT}.$$

$$\frac{a''}{a_o} = \frac{z^2 T^2}{2} e^{-zT}. \quad (\text{III}). \text{ This is the fraction of } a_o$$

remaining in Tank No. 3 after time  $T$  rated from the entrance of  $a_o$  into the system. From the above we have  $v_1 = e^{-zt}$ ,  $v_2 = e^{-zt} zt$ ,  $v_3 = e^{-zt} \frac{z^2 t^2}{2}$ . The general expression for  $v_n$  ( $n$  being greater than 1) is

$$v_n = e^{-zt} \frac{(zt)^{n-1}}{1.2.3 \dots (n-1)}.$$

If we let  $V_1, V_2, V_3 \dots V_n$  be the total fraction of  $a_o$  remaining in the first tank; first two tanks, first three tanks, ... first  $n$  tanks, then

$$V_n = e^{-zt} \left( 1 + zt + \frac{z^2 T^2}{2} + \dots + \frac{(zt)^{n-1}}{1.2.3 \dots (n-1)} \right).$$

This is the general formula for the fraction of  $a_o$  remaining in a system of  $n$  tanks after time  $T$ , rated from the entrance of  $a_o$  into the system.

#### Importation of Optical Glass Controlled by the Government

The importation into the United States of French optical glass is to be controlled by the Government. American manufacturers and importers desiring this glass must place their orders through the War Industries Board and the War Trade Board. Direct orders will lack the government approval and necessary endorsements to allow the importation.

Regulations for the importation of French optical glass adopted following conferences between the Military Optical Glass and Instruments Section of the War Industries Board, of which George E. Chatillon is chief, and the Bureau of Imports of the War Trade Board, provide:

1. All import orders for French optical glass should be placed with the Service Geographique, who will distribute them among the various French manufacturers.
2. The order, together with the application for import licenses, should be forwarded to the War Trade Board, Bureau of Imports, to the attention of Mr. Rearson.
3. The applications should state in detail the purpose for which the glass is intended.
4. The War Trade Board will in all cases consult with the Military Optical Glass Section of the War Industries Board before applications are granted.
5. Orders placed direct will not have the approval of the Military Optical Glass Section nor the necessary endorsement of the War Trade Board to allow the glass to be imported from France.
6. If glass of a special manufacturer is desired, it may be noted on the order.

#### Production of Hand Grenades

Major General C. C. Williams, chief of ordnance, has written the Single Service Package Corporation of New York City, commending the employees of that plant for having attained a production speed of more than 100 hand grenades a minute.

The third million of grenades made by this concern was shipped to France the middle of last month, having been produced in exactly one month's time. During the week ending September 14, the plant shipped a total of more than 300,000, or 55,000 a day, Saturday being counted as four-ninths of a day, and this despite the fact that the plant was closed down ahead of time September 12 to permit employees to register under the Selective Service draft act. The maximum production was attained Friday, September 13, when 55,200 grenades were turned out. Simple as a completed grenade seems, it requires twenty-five distinct operations.

# Commercial Uses of Chlorine\*

A Review of the Direct and Indirect Applications of Chlorine in Independent Uses, Metallurgy, Poisonous Gases, Inorganic Salts and Organic Solvents, Pharmaceuticals and Intermediates

By V. R. KOKATNUR

THE electrolytic manufacture of caustic soda during the last decade or so has brought such new problems to the fore, which if not solved immediately seem to threaten the very life of the industry that has given them birth. The electrolysis of brine produces caustic soda, hydrogen and chlorine. Caustic soda produced by the Solvay Process is decidedly cheaper than electrolytic caustic, while electrolytic chlorine can be made cheaper than chlorine made by other methods.

Thus it is easy to see that the success of the electrolytic alkali industry depends not so much upon the profits obtained from caustic as upon those from chlorine. Though the main object in the electrolysis of brine is caustic soda, chlorine thus assumes a greater importance in the electrolytic alkali industry. In other words, the evaluation of the products of electrolysis of brine depends not so much on our motive of electrolysis as on the practical side of the question. Hence chlorine becomes important as a primary-product, since among the products of electrolysis, it is at the same time the most important and the cheapest.

After all, the question whether a product should be called a primary-product or a by-product is settled by its cheapness of manufacture and its utility, and from this standpoint chlorine can be called a primary-product and not a by-product. While hydrogen can be thrown away without much detriment to the neighboring community, chlorine cannot be so dealt with, even if it was so desired, on account of the damage suits such a step might involve. In addition we cannot afford to throw it away since electrolytic caustic cannot successfully compete with Solvay caustic unless its allies, hydrogen and especially chlorine, reinforce and strengthen its ranks.

We are thus confronted with the double necessity of utilizing chlorine, first because we cannot afford to throw it away, and secondly because we cannot throw it away, even if we wanted to, without serious trouble. The unprecedented stimulus given to the chemical industry as a whole by the present war, and its certain growth after the war, will undoubtedly expand the electrolytic alkali industry far beyond its present confines.

Such a growth will result in an enormous production of chlorine. The present consumption of chlorine in the production of bleaching powder or hydrochloric acid cannot further be extended without seriously overflowing the world's markets. Besides it is not profitable. Thus we are confronted with a problem most vital to the life of the alkali industry—a problem which is fraught with grave consequences and pregnant with possibilities; a problem of finding new and profitable

uses of chlorine—and if this problem is not solved, it will mean slow but sure death to the industry.

This paper does not claim any originality in its contents. Its main object is to present a systematic treatment of the possible ways of utilizing chlorine, showing the avenues and by-paths. Some of these by-paths show signs of considerable traffic, while others are hardly used and show but few footprints. The known roads are the ones that are followed by many as they offer the least resistance. None but the daring explore the new roads lest they lead them astray to be lost in the wilderness. As in everything else, it is the new road that opens up fields of profitable endeavor and the chlorine industry is no exception.

This table shows the classification of the different ways of possibly utilizing chlorine. Some of these look like footpaths and have a small and limited application, while others appear like beautiful and broad avenues, on which one can travel far and wide, nay, can even cross the continent.

## DIRECT USES

### 1. INDEPENDENT USES

Among these may be mentioned its use as a bleaching agent in water solution in the textile and paper industries.

It finds use as a disinfectant and sterilizer of potable water, whereby typhoid, cholera and other epidemic diseases are completely eliminated from cities wherever it has been used.

Recently it has been used in the treatment of wounds and their asepsis through what is known as Dakin-Carrel solution.

Liquid chlorine is known to have been used in gas-warfare in producing smoke-screens or clouds.

It can be used in fumigating houses, thus destroying the microbes of plague and other diseases.

It is used in sewage treatment and also in sterilizing raw-hides.

### 2. CHLORINATION OF ORES

There have been many patents on the chlorination of ores for specific purposes in metallurgy. Here seems

\*Read before the American Electro-chemical Society at Atlantic City, N. J., Oct 1, 1918.

to be a vast field, as a large tonnage of chlorine will be consumed, if in any such line it may find application.

It has been used for the separation of gold or silver from base metals and thus finds an indirect application in the metallurgy of gold and silver.

It is also used in separating copper from nickel, *i. e.*, in the metallurgy of both copper and nickel.

It is used in separating tin as tin-tetra-chloride from tinned iron-scrap by what is known as Goldschmidt's Detinning Process.

It finds application in the extraction of valueless ore-residues, which could not be profitably worked out except by the use of chlorine. Thus a low percent-ore can be worked out successfully to advantage by its use and its valuable metal contents be made available for our use.

The chlorination of ores can be extended *ad infinitum* to newer fields of adventure, taking advantage of the volatility of certain chlorides and the action of chlorine on different metals and metallic oxides. Thus perhaps iron-pyrites may be used for iron manufacture and feldspars may some day give us our potash and aluminium.

### 3. POISONOUS GASES

Gas warfare is perhaps the most unforeseen development of the present war and opens up interesting fields. It is interesting to note that more than fifty per cent of the gases known to be used in the present war are chlorine compounds.

Silicon-tetra-chloride ( $\text{SiCl}_4$ ) and titanium-tetra-chloride ( $\text{TiCl}_4$ ) are used in producing smoke-screens. Chloro-sulphonic acid ( $\text{SO}_2\text{HCl}$ ) used in hand-grenades and smokepots. Phosgene ( $\text{COCl}_2$ ) is used in shells as an offensive gas. Chloroacetone ( $\text{CH}_3\text{ClCOCH}_3$ ) and trichloro-methyl-chloro-formate ( $\text{Cl-COOCCl}_2$ ) known as superpalate are used in shells as lachrymators. Benzyl-chloride ( $\text{C}_6\text{H}_5\text{-CH}_2\text{Cl}$ ) is used as a tear-gas in shells; chloropicrin or nitrochloroform ( $\text{C}(\text{NO}_2)_3\text{Cl}$ ) also as a tear-gas in shells, mustard gas, *i. e.* dichlorodiethyl-sulphide ( $(\text{C}_2\text{H}_5\text{Cl})_2\text{S}$ ), in shells for both offensive and neutralization, diphenylchlorarsene ( $(\text{C}_6\text{H}_5)_2\text{AsCl}$ ) in shells as a "sneezing gas"; phenyl-carballymine-chloride ( $\text{C}_6\text{H}_5\text{NCCl}$ ) in shells as a lachrymator; dichloromethyl-ether ( $(\text{CH}_3\text{Cl})_2\text{O}$ ) in shells and methyl-chloro-sulphonate ( $\text{CH}_3\text{ClSO}_3$ ) in hand-grenades.

Other so-called gases are benzyl-bromide ( $\text{C}_6\text{H}_5\text{CH}_2\text{Br}$ ) used in shells, bromoacetone ( $\text{CH}_3\text{BrCOCH}_3$ ) in hand grenades, bromo and dibromoketones like ( $\text{CH}_3\text{BrCOC}_2\text{H}_5$ ), ( $\text{CH}_3\text{COCHBrCH}_2\text{Br}$ ) in shells; xylbromide ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$ ) in shells; allylthio-cyanate ( $\text{C}_3\text{H}_5\text{-NCS}$ ) in shells; dimethylsulphate ( $(\text{CH}_3)_2\text{SO}_4$ ) in hand grenades, and sulphur-tri-oxide, ( $\text{SO}_2$ ) in hand grenades and shells. It has recently been found that cyanogenchloride ( $\text{CNCl}$ ) and butyl-mercaptan ( $\text{C}_4\text{H}_9\text{-SH}$ ) are also used.

It will be noticed here that many of these non-chlorine gases are capable of being produced from chloro-compounds, *i. e.*, using chlorine in intermediate steps. For example, allylthiocyanate can be prepared from allylchloride and potassium sulphocyanate ( $\text{KCNS}$ ); methylsulphate from methyl-alcohol and sulphuryl-chloride; benzyl-bromide from benzyl-chloride and potassium bromide ( $\text{KBr}$ ). Hence it would not be far from truth to say that more than 95 per cent of the

poisonous gases can be made directly or indirectly by the use of chlorine.

It is to be regretted that these gases should have been used for incapacitating or destroying human beings, when if intelligently directed they might well serve a useful purpose. There is no reason why they could not be made to save us and our crops from the ravages of microbes and insects, as they are saving us today from the ravages of Prussian militarism. We must not forget that our worst enemies turn out to be our best friends when properly controlled and directed just as some of the worst poisons, like strychnine and morphine, have proven to be.

### 4. INORGANIC CHLORINE COMPOUNDS

There are many metallic and non-metallic chlorides that have found an extensive application in arts and industries. Chloride of lime or bleaching powder, as it is sometimes called, is used extensively in bleaching, as its name indicates. It is used also in purifying water, as a disinfectant, and in many cases as an oxidizing agent. It is also used advantageously in chlorination of basic substances, like amines, to produce chloramines, and often gives quite different results from ordinary chlorination.

Sulphur-mono-chloride ( $\text{S}_2\text{Cl}_2$ ) is used extensively in vulcanizing rubber, making rubber substitutes from oils and fats and preparing the surface of thousands of useful articles. It is also used in defatting cane-juice (sugar refining). It can be advantageously used in the preparation of chlorides free from oxychlorides. It may also find application in preparing organic sulphides.

Sulphuryl-chloride ( $\text{SO}_2\text{Cl}_2$ ) and thionyl-chloride ( $\text{SOCl}_2$ ) can be used in the preparation of acid chlorides from acid salts and as chlorinating agents. Sulphuryl-chloride can be used in the manufacture from sodium acetate of acetic anhydride, an invaluable ingredient in the manufacture of dyes, cellulose acetate and many other drugs.  $4\text{CH}_3\text{-COONa} + 2\text{SO}_2\text{Cl}_2 = 2(\text{CH}_3\text{CO})_2\text{O} + 2\text{NaCl} + \text{Na}_2\text{SO}_4$ .

Phosphorus chlorides such as phosphorous trichloride ( $\text{PCl}_3$ ), phosphorous pentachloride ( $\text{PCl}_5$ ), and phosphoryl or phosphorous oxychloride ( $\text{POCl}_3$ ) are all used as chlorinating agents, particularly valuable for the substitution of hydroxyl or oxygen by chlorine. Thus they can be used to prepare ethyl-chloride from alcohol or ether and acid-chlorides from fatty acids.

Antimonytrichloride or butter of antimony ( $\text{SbCl}_3$ ) is used as a caustic in medicine, in the preparation of tartar-emetic and as a "bronzing" solution for gun barrels and other instruments. Antimony-pentachloride is often used as a chlorinating agent to serve the purpose of phosphorous chlorides.

Anhydrous aluminium chloride is used extensively in organic synthesis and recently has found application in the "cracking" of petroleum oils to obtain gasoline. Ferric-chloride can be used for similar purposes.

Tin-tetra-chloride ( $\text{SnCl}_4$ ) is used in cotton-printing and silk dyeing, while stannous chloride ( $\text{SnCl}_2$ ) has an extensive use as a reducing agent. Zinc chloride is used for the impregnation of telegraph poles and railway ties to prevent rot, and also in vulcanizing fiber goods. Zinc oxychloride is used as a cement in dentistry.

Mercuric chloride ( $\text{HgCl}_2$ ) and calomel ( $\text{Hg}_2\text{Cl}_2$ ) are both used as antiseptics and in medicine. Silver-chlo-

ride in its colloidal form is used extensively in photography. Other chlorides have not yet found industrial application.

Sodiumhypochloride is used extensively in solution for bleaching and as an antiseptic, but if solid sodiumhypochloride could be produced it would be extremely valuable. So far no attempt seems to have been made in this direction, but the day is not far distant when it will be manufactured in large quantities.

Different chlorates like those of sodium, potassium, calcium and barium are used in the manufacture of matches, cartridges, fireworks, dyes and as lozenges for sore throat.

Perchlorates also are being used more and more. Ammoniumperchlorate is perhaps the most economic and at the same time the most terrific of explosives. It is destined to play, in the near future, an important part in industries like mining, especially as there is a great shortage of animal fats, glycerin from which goes to make our dynamites. It is surprising that our government should not have taken any steps in this direction.

##### 5. ORGANIC COMPOUNDS

Chlorine finds an extensive use in various organic compounds as tabulated below under various sub-headings.

*c. Coal-tar intermediates:* Among the most important coal-tar intermediates may be mentioned a derivative of benzene called chlor-benzene, or, as it is sometimes wrongly called, chlor-benzol. It finds an extensive use in the dye industry and in the manufacture of picric acid. Dichlorobenzenes have not so far found any industrial application. It is needless to say that the still higher chlorobenzenes are worse off in this respect. It seems that mono-chlor-benzenes may find application as a solvent, as it can be manufactured cheaply and as it is a more stable compound than aliphatic chlorides, which generally decompose in the presence of moisture and light.

Chlor-toluenes like benzyl-chloride ( $C_6H_5CH_2Cl$ ) can be used to make benzyl-alcohol, which has a good demand in the essential oil industry. Benzol-chloride ( $C_6H_5CHCl_2$ ) is used to manufacture synthetic oil of bitter almonds or benzaldehyde, which is also used in vast quantities in the perfume industry. Benzotrichloride or phenylchloroform ( $C_6H_5 \cdot CCl_3$ ) is used to manufacture benzoic acid. Chlorobenzoic and salicylic acids have a limited application.

Chlorphenols and cresols are used in synthetic work. Recently some chlor-naphthalenes have been used as solvents and in making waxy condensation products for insulation purposes. Chlor-naphthalenes may open up new fields for the dyes of naphthalene series. Chloranilines have a limited application in the dye industry, while chloranil or tetrachlorobenzoquinone has a great demand. The chlorination of anthracene may also open up new fields in the dye industry.

Chlor-acetic acids also are extensively used in dye manufacturing. Monochlor-acetic acid plays an important part in the synthesis of indigo. Dichloroacetic acid is used in the synthesis of isatin. Trichloroacetic acid is used extensively in medicine.

Phosgene ( $COCl_2$ ) is used in triphenylmethane dyes and in the synthesis of acids and ketones, especially Michaeler's Ketone.

*b. Pharmaceutical chemicals:* Very little attempt has been made to bring chlorine compounds of pharmaceutical value on the market. In this line chloroform must be mentioned as one being extensively used as an anesthetic. It is also used as an antiseptic and is even used internally in medicine. It is also used in dentistry.

Chloral ( $CCl_3CHO$ ) finds application as a hypnotic or soporific. Both chloral and chloroform are at present very expensive and a cheaper method of manufacture would be a boon to humanity.

Methylene-chloride finds some use as a local anesthetic. Ethyl-chloride is used also as a local anesthetic, and in conjunction with others in some form as a hypnotic. Isopral or trichlorisopropylalcohol ( $CCl_3CHOH \cdot CH_3$ ), chloramide or chloralformamide ( $CCl_3CHOH \cdot NH \cdot CHO$ ), chloralimide ( $CCl_3CHNH$ ) and dormiol ( $CCl_3CH(OH)O \cdot C_2H_5$ ) are used in various ways in pharmacy. Ethylene-chloride ( $C_2H_4Cl_2$ ), or "Dutch Liquid," is used as an inhalant and local anesthetic.

Chloretone or acetone-chloroform ( $CCl_3(CH_3)_2COH$ ) is used as a local anesthetic in conjunction with cocaine and adrenaline. Chlor-phenols and cresols are antiseptics of great value, being several times stronger than phenols and cresols and yet are free from their toxic effects. Some chlorinated oils have been tried in Europe for their medicinal value.

Many chlorine compounds like hexachlor-ethane and hexachlor-benzene are likely to be useful either as antiseptics or vermicides, or in both. They may find extensive application in the washing and sterilization of milk cans, as chlorine-solvents are good fat-extractors and antiseptics at the same time.

Dichloramine-T or p-toluene-sulphon-chloramide has been recently used by Drs. Dakin and Carrel in the asepsis of wounds. It is a non-irritating, synthetic germicide and corresponds to the antiseptic chloramine substances that are formed when hypochlorous chlorine is brought in contact with the exudate of suppurating wounds. It can be used in doses twenty to forty times stronger than in hypochlorite solution. It has absolutely no destructive effect on tissue-cells like tincture iodine. It is used also as a nasal antiseptic. It has been found to be better than bleaching powder for the purification of water, because of its stability in solution, non-toxicity, absence of corrosive action and non-production of unpleasant taste.

*a. Solvents:* The most extensively used chloro-solvent is carbon-tetra-chloride ( $CCl_4$ ), a compound which is made by the action of chlorine or sulphur-mono-chloride on carbon bisulphide ( $CS_2$ ). It is used as a solvent in the rubber industry and for the extraction of fats. It is also used in dry-cleaning and in fire-extinguishing mixtures like "Pyrene."

Chloroform ( $CHCl_3$ ) is used to a limited extent as a solvent in electrotechnics in the rubber-industry and in photography. Methylene-chloride, though a good solvent, has not been widely used.

Ethylene-chloride or "Dutch Liquid" ( $C_2H_4Cl_2$ ) is a solvent of great value. It resembles carbon-tetrachloride in most respects and is a good solvent for cellulose acetate. It can be made cheaply by chlorinating ethylene gas obtained by either "cracking" oil gas or by limited hydrogenation of acetylene. Besides being a solvent of great value, it is very useful in the synthesis

*d. Synthetic intermediates:* There are many organic chlorine compounds, which though incapable of being used as such in arts and industries, are nevertheless very useful as intermediate products in the manufacture of other commercial products. Most chloro-hydrocarbons can be used to make unsaturated hydrocarbons of value. Organo-metallic compounds like zinc methyl ( $\text{Zn}(\text{CH}_3)_2$ ) and magnesium-methyl-chloride are useful for preparing synthetic hydrocarbons, secondary and tertiary alcohols and fatty acids.

Trichloropropane or trichlorohydrin ( $\text{CH}_2\text{ClCHClCH}_2\text{Cl}$  B.P.  $158^\circ$ ) though in itself not very useful, forms the basis of the synthesis of glycerol, a product of immense value in arts. Amylchloride and dichloropentane are useful in the synthesis of amylalcohol, amylacetate and isoprene.

$\text{H}_3\text{C} \searrow \quad \text{C} = \text{C} \quad \text{CH}_2$   
 $\text{H}_3\text{C} \nearrow \quad \quad \quad \text{H}$  Both amylalcohol and amylacetate are used extensively in the celluloid industry, while isoprene forms the parent substance of rubber, a substance which has entered into many phases of human needs.

Chloro-acetons can be used for the synthesis of citric acid or of glycerol. Monochloralkyls or chlorohydrocarbons can be used to build up higher hydrocarbons or for the introduction of alkyl groups in other organic compounds. Various acid chlorides like acetyl chloride or benzoyl chloride are used to make acid anhydrides or for the introduction of acetyl or benzoyl radicals.

The chlorine compounds are so vital in organic chemistry that but for their help directly or indirectly very few organic compounds could be prepared. Neither the amino group  $\text{NH}_2$ , nor the sulphonic group  $\text{HSO}_3$ , neither the sulphite radical  $\text{SO}_2$  nor the hydroxyl acid radical  $\text{OH}$ , neither the nitro group  $\text{NO}_2$  nor the nitrite radical  $\text{NO}$ , neither the acetyl radical  $\text{CH}_3\text{CO}$  nor the carboxyl group  $\text{COOH}$ , neither the alkyl nor the alkoxy group, can be substituted without their help. In fact, if any process is more useful, far-reaching and universal in application in organic chemistry it is chlorination. The halogens are the most intimate friends of the hydrocarbons and without their consent and coöperation no work of any kind is undertaken by hydrocarbons themselves.

If I may here be permitted to mention a personal experience in teaching, I would like to relate my experience in explaining the behavior of various hydrocarbons in organic chemistry.

To remove the confusion regarding the behavior of saturated and unsaturated hydrocarbons, I compared the saturated hydrocarbons to wealthy and completely self-satisfied people, while I called the unsaturated hydrocarbons needy beggars. Now beggars accept gifts but do not give anything in return. Saturated hydrocarbons on the other hand being "rich" are always ready, if they need anything, to give something in return. But the trouble is that they already have everything and need nothing. Hence they are the hardest to be induced to do anything. The only way to make them act as you desire is to approach them, not directly, but through their most intimate friends, the halogens, just as you have to have a "pull" to get a politician to do you a favor. If you can reach them through a friend they will do anything for you.

Among the indirect uses of chlorine can be mentioned its value as an oxidizing agent. Thus it can be used

to make potassiumpermanganate from potassium manganate,  $2\text{K}_2\text{MnO}_4 + \text{Cl}_2 = 2\text{KMnO}_4 + 2\text{KCl}$ . It can be used in the manufacture of potassium ferri-cyanide from potassium ferro-cyanide.  $2\text{K}_4\text{Fe}(\text{CN})_6 + \text{Cl}_2 = 2\text{K}_3\text{Fe}(\text{CN})_6 + 2\text{KCl}$ . A similar application can be found in making lead peroxide from litharge or lead acetate (sugar of lead);  $\text{PbO} + \text{MgO} + \text{Cl}_2 = \text{PbO}_2 + \text{MgCl}_2$  or  $\text{Pb}(\text{OOCCH}_3)_2 + 2\text{HCl} = \text{PbO}_2 + 2\text{CH}_3\text{COOH} + \text{Cl}_2$ . Similarly superphosphate can be made from phosphate.  $\text{Ca}_3(\text{PO}_4)_2 + 2\text{SO}_2\text{Cl}_2 + 4\text{H}_2\text{O} = 2\text{CaSO}_4 + \text{Ca}(\text{H}_2\text{PO}_4)_2 + 4\text{HCl}$ . It can be used in making artificial camphor from Isoborneol, which in turn can be made from turpentine or pinene.

By its use pure cellulose can be obtained from wood-pulp.

Dr. Wintlein mentions an experiment whereby 100 parts, by weight, of dried pine-wood, treated by lime and chlorine, gave 50 parts, by weight, of pure cellulose. Bleaching powder can be used to produce pure oxygen gas from what is technically known as lavosite.

Thus it can be seen that chlorine has an extensively wide application in both inorganic and organic industries and supplies many human wants. It bleaches our linen, purifies our water, protects us from epidemic diseases and helps us in making dentistry and surgery painless. It is our companion in homes, companion in camp, companion in peace and companion in war.

The end of this war will find an enormous excess of chlorine in this country and the problem of turning this vast otherwise nuisance material into useful channels will be before us. The electrolytic alkali manufacturers of this country will do well to think and not wait until they are face to face with it. We must remember that a stitch in time saves nine. A little foresight and forethought will go a long way in helping to solve this problem.

Some manufacturers think that if they seek today new applications for their by-products they would be trespassing on the field of their present customers who are buying chlorine. But it should be remembered that a customer buys chlorine only when he can make money for himself. He makes only such chlorine products as are in demand at a good price. He is not interested in buying chlorine to find new uses for it. Consequently he is not the man to experiment. As a matter of fact it is the manufacturer who lives or dies and who is the one most concerned. It is up to him to sound the depth of this unexplored region.

### Basic Exchange in Permutite

Rothmund and Kornfeld in *Zeitschrift anorg. Chemie* 103, pp. 129-163, state that the basic exchange which takes place between hydrated aluminosilicates, such as the soil zeolites or the artificial product permutite, and neutral salt solutions is a true chemical substitution of an alkali metal for an earth and not a process of adsorption. In the case of permutite, equilibrium is rapidly established between the solid and a neutral salt solution, and the composition of the resulting permutite is found to depend upon the relative concentrations of the interchangeable bases in solution.

## The Development of the Ferro-Manganese Industry in the United States Since 1914\*

By THEODORE SWANN

PRIOR to 1914 the United States produced less than one-half of its ferro-manganese requirements, and in 1914 only 54% out of a total 183,728 tons of ferro-manganese produced and imported. In 1917 the total production and imports increased to 331,381 tons, of which 286,000 tons, or 86%, was produced in the United States, and in 1918 the percentage of home production will not be less than 90%.

### SOURCES OF MANGANESE SUPPLIES

It is well known that under pre-war conditions the world's supply of manganese ore came mainly from Brazil, India and Russia. Thus the shortage of shipping brought about by the war made it necessary that the United States develop to the greatest extent possible its own manganese ore resources.

The production of manganese ore in the United States in 1914 was 2635 tons; this was insufficient to make one-half of one per cent of the ferro-manganese required.

In 1915, domestic production of manganese ore increased to 9709 tons, or enough to make about two per cent of our requirements. During 1916 the domestic production increased more than treble that of the previous year, we producing 26,997 tons of manganese ore, or enough to make less than three per cent of our increased ferro-manganese requirements. In 1917 the production of high-grade domestic ore quadrupled that of the previous year's output. We produced 113,734 tons of high-grade manganese ore, or enough to make over 10% of the ferro-manganese required.

The domestic ore production of 1917 only supplemented the foreign ores, the shipment of which was rapidly becoming more difficult. During the first six months of the present year 1918, we find the high-grade domestic manganese ore production greater than that of the entire year of 1917, with prospects for decided increase in the second half over that of the first half.

### PRODUCTION OF FERRO-MANGANESE

During July, 1918, a total of 30,370 tons of ferro-manganese was produced containing 20,226 tons of metallic manganese; 23,021 tons of spiegeleisen was produced containing 4698 tons of metallic manganese, making a total of 24,924 tons of metallic manganese in the total ferro-manganese and spiegeleisen produced. The percentage of metallic manganese derived from domestic ores in the above tonnage for July 1918 was 47.9 per cent.

It has been estimated from the consumption to date this year that the iron and steel industry will require during the remainder of this year and the first half of 1919, 31,000 tons per month of metallic manganese in the form of ferro-manganese and assuming that the average grade will be 65%, the monthly requirements of ferro-manganese will be 32,300 tons; in addition 3000 tons per month of metallic manganese in the form of

spiegeleisen will be required; assuming the average grade to be 18% the monthly requirements will be 16,500 tons.

The total metallic manganese requirements for the year ending June, 1919, for both ferro-manganese and spiegeleisen are therefore assumed to be 288,000 tons; from the best information available at this time the United States will produce ores that will contain at least 50% of the manganese content required to make this tonnage of ferro-manganese and spiegeleisen.

At the May meeting of the American Iron and Steel Institute, Mr. C. R. Ellicott presented a most complete and instructive paper, entitled, "The Conservation of Manganese." In addition to the facts so ably presented by Mr. Ellicott, we desire to pay tribute to the many producers of domestic manganese ore who by their efforts are rapidly making the United States less dependent upon other countries for our supply of manganese ores. We strongly urge that it is the patriotic duty of both the producers and users of manganese alloys to encourage in all ways possible the production of domestic ores and to further break away from the old prejudice against the use of lower grade alloys.

### ADVANTAGES OF SILICO-MANGANESE ALLOYS

It has been suggested that the steel industry could further aid in the conservation of shipping by using, when possible (in many instances to their direct advantage), silico-manganese which could be made from high silica domestic ores. Some of our prominent metallurgists consider the advantages of silicon alloyed with manganese to be:

First: The silicon forces down the carbon, giving the desired low carbon alloy for the steel addition.

Second: As a dioxidizer the combined selective action of silicon and manganese will be more active as a dioxidizer than either element alone.

Third: The resultant combined oxides forming manganese silicate will, due to its greater fluidity, be eliminated from the metal more readily than the oxides of either alone.

There are numerous deposits of manganese ore too high in silica to be used in making ferro-manganese. These however, are available for making silico-manganese.

### MANGANESE SLAGS

It is possible to make silico-manganese from high slags carrying from 10% and up of manganese and also from manganese ores carrying as low as 18% manganese and as high as 40% silica. While it is not so attractive commercially to use slags and very long manganese ores, this source of supply has been proven to be available by one electric furnace producer. This producer made from slags, running 10 to 17% manganese, several carloads of silico-manganese analyzing about 64% manganese, 12% iron, 23% silicon, and 0.60% carbon. It may be of interest to note that the average slags produced with the above metal run under 4% in manganese.

The manufacture of ferro-manganese in the electric furnace is one of the important developments in connection with the utilization of domestic manganese ores, especially where the plants are located near the ore mines. Not only are such plants conserving ocean transportation, but railway transportation as well.

\*Abstract of paper presented at the Fourth National Exposition of Chemical Industries, Sept. 27, 1918.]

Perhaps the greatest value today of the electric furnace producing ferro-manganese, is the conservation of coke. The majority of electric furnaces are operated and heated by hydro-electric power instead of coke as in the blast furnace.

In July, 1918, over 7½% of the entire production of ferro-manganese was made in the electric furnaces. It is estimated that by the end of this year electric furnaces will be producing about 15% of the total ferro-manganese produced in the United States.

The slag and volatilization losses in the smelting of the ferro-manganese is an ample field for the conservation of our manganese supply. The fundamental causes underlying such losses are problems to be further worked out by our metallurgists. It is believed that it is possible so to improve the past general average practice as to increase the recovery by 10%. If such increase could be made, it would save about 30,000 tons of metallic manganese and thus release over 75,000 tons of shipping.

## Increased Production of Artificial Abrasives

A MARKED increase in the output of artificial abrasives in the first half of 1918, as compared with the first half of 1917, is shown by figures compiled by Frank J. Katz, of the United States Geological Survey, Department of the Interior, and obtained in coöperation with the Mines Branch of the Canada Department of Mines. There was little change in the output of corundum and a decrease in the output of emery.

### EMERY AND CORUNDUM

During the first half of 1918 emery ore was produced by seven operators in the Peekskill district, in New York, and by one in southern Virginia. Corundum is produced from one mine in Macon County, N. C., and by one company operating in Renfrew County, Ontario. The combined mine output of emery and corundum in the United States and Canada from January 1 to June 30, 1918, was 5455 short tons. During the same period the producers sold, shipped, or used in the manufacture of abrasive articles approximately 4500 short tons, and the stock on hand at the mines June 30 was about 1500 short tons. As compared with the same period in 1917, there was a large decrease in the quantity of emery mined, and the output from January to June, 1918, inclusive, was considerably less than half of the mine output of emery for the entire year 1917. During the first half of 1918 corundum was produced at about the same rate as in 1917.

### ARTIFICIAL ABRASIVES

Artificial carbide abrasives, including carborundum, crystolon and carbolon, were produced during the first half of the year 1918 by two companies in the United States, operating plants at Niagara Falls, N. Y., and at Blasdell, N. Y., and by three in Canada, operating plants at Shawinigan Falls, Quebec, and at Chippewa and Thorold, Ontario. The plant output of crude carbide abrasives was 6583 short tons. During the same period the producers sold or used in the manufacture of abrasive materials 5633 tons, and on June 30 there remained in their hands as stocks 2840 tons.

Aluminium oxide abrasives, including alundum, aloxite, exelon, lionite and natite, were manufactured in the United States by four companies, three of which operated plants at Niagara Falls, N. Y., and one at Blasdell, N. Y., and in Canada by five companies, which operated plants at Niagara Falls, Chippewa and Thorold, and two at Hamilton, Ontario. The combined output of these plants in the first half of 1918 was 28,341 short tons. During the same period the producers sold or used in the manufacture of abrasive materials 23,161 short tons, and on June 30 there remained in their hands 26,221 short tons. The combined figures for carbide and alumina abrasives for the first half of 1918 are: Manufactured, 34,974 short tons; material sold or used, 33,794 short tons; and stock in hands of producers June 30, 29,061 short tons. As compared with the first half of 1917, there was an increase in production of nearly 60 per cent. The production in the first half of 1918 was approximately equal to 62 per cent of that for the whole year 1917.

## Consumption of Chlorine Bleach Curtailed

SPECIFIC reductions in the use of chlorine bleach in any form in the pulp and paper industry have been agreed upon by the Pulp and Paper Division of the War Industries Board and will shortly become legally effective as follows:

### SULPHITE PULP

The use of chlorine by any individual user in the bleaching of sulphite pulp is restricted to an amount not greater than 40 per cent of the amount now being used; that is to say, the amount of chlorine contained in 35 per cent commercial bleaching powder now used per 100 pounds of sulphite pulp will be computed and the user will be allowed 40 per cent of this amount in each 100 pounds of sulphite pulp hereafter bleached. Variation in the use of bleach per 100 pounds of sulphite pulp is permitted for the purpose of maintaining uniform color, provided the average used per 100 pounds of the pulp bleached does not exceed the permitted use of bleach per 100 pounds.

### SODA PULP

The use of chlorine by any individual user in the bleaching of soda pulp is restricted to an amount not greater than 70 per cent of the amount now being used; that is to say, the amount of chlorine contained in 35 per cent commercial bleaching powder now used per 100 pounds of soda pulp will be computed and the user will be allowed 70 per cent of this amount in each 100 pounds of soda pulp hereafter bleached. Variation in the use of bleach per 100 pounds of soda pulp is permitted for the purpose of maintaining uniform color, provided the average used per 100 pounds of the pulp bleached does not exceed the permitted use of bleach per 100 pounds.

### SULPHATE PULP

The use of chlorine in the bleaching of sulphate pulp is specifically forbidden.

### OLD PAPERS, ALL KINDS

The use of chlorine in the bleaching of recovered old papers is restricted to 0.35 per cent of stock.

# Chemical Control of Water Softeners

## A Discussion of the Reactions Involved in the Lime-Soda-Ash Process and the Derivation of a Practical and Simple Field Routine Analysis

By LOUIS F. CLARK

THE process of softening water by the use of the reagents, calcium hydrate or oxide, lime, together with sodium carbonate, soda ash, is a venerable one. The fundamental chemistry of the process and the machinery by which it is applied, may be found described in textbooks on analytical chemistry. Local conditions, however, often demand a special and convenient method of control for the process. The method as herein set forth has been evolved by reason of the following conditions:

1.—The water to be treated is subject to seasonal variation.

2.—The water is treated at widely distributed stations, so that the various machines require individual regulation.

3.—The lime used in the machines has a variable CaO content depending on the degree of calcination.

4.—The soda ash ranges from 45 to 90 per cent Na<sub>2</sub>CO<sub>3</sub>, according to the time it has effloresced in dry air.

5.—The operation of the individual softening machines must be controlled by an operator who can make field tests to determine the proportions of materials required.

6.—The equipment for conducting the tests must be simple and portable.

7.—The operator usually will have available only the water to be softened, as he will carry no distilled water.

An average analysis of the hard water to be softened will show that it is of such composition that any substitution process, whereby the scale-forming alkaline earth salts are precipitated and those of sodium substituted, will leave such an enormous amount of material in solution after treatment that evaporation residues will require frequent removal. Thus it is urgent that the individual softening machines receive careful regulation to avoid possible excesses when precipitants of such variable composition are in use.

### AN AVERAGE WATER ANALYSIS

|                     | Million | Grains,<br>U. S. Gal. |
|---------------------|---------|-----------------------|
| Silica              | 28.0    | 1.63                  |
| Sodium Chloride     | 156.2   | 9.11                  |
| Magnesium Chloride  | 19.2    | 1.12                  |
| Magnesium Sulphate  | 318.1   | 20.32                 |
| Calcium Sulphate    | 618.0   | 36.04                 |
| Calcium Bicarbonate | 202.0   | 11.78                 |
|                     | 1371.8  | 80.00                 |

Hardness tests on water by the use of soap solutions do not determine the exact quantities of reagents necessary for softening. A field analysis may be made by titration of the water with a suitable HCl solution, together with proper additions of the various reagents actually used in the softening process. It is of first importance that the HCl solution used should be of such strength that in any titration the operator can read directly from the burette in pounds per 1000 gallons, or a simple multiple thereof, because the machines require the weight of the precipitants in pounds for each 1000 gallons of water to be treated.

The most satisfactory report of a water analysis is given when the components are expressed as parts per million. If we accept the specific gravity of the water as unity, we may accept milligrams per liter as equal to parts per million. By the relation of weights we can arrive at the factor,<sup>1</sup> 0.0583, by which parts per million should be multiplied to give grains per U. S. gallon; further if we consider gms. of materials in solution in 100 cc., we may multiply such weight by 83.3 and get pounds per 1000 gallons.

Other points it is necessary to consider here are that, as will be subsequently shown, it is convenient to consider the lime as having a certain percentage of CaO content rather than Ca(OH)<sub>2</sub>, even though the material has been slaked, by reason of the fact that the molecular weight of CaO (56) is nearly equal to one-half the molecular weight of Na<sub>2</sub>CO<sub>3</sub> (106), at least sufficiently near, that our HCl solution can be adjusted so that its factor for lime will be one-half its factor for soda ash. Finally, the calcium in solution in this water in excess of that satisfied by the mineral acids is regarded as being in solution as bicarbonate, not carbonate. Basicity determination on the water on this assumption checks the value of calcium so existing, calculated from a complete analysis.

With these points in view we can proceed to calculate the strength of hydrochloric acid solution required.

Assume K = gms. Ca(HCO<sub>3</sub>)<sub>2</sub> in 100 cc. raw water.

Let x = gms. CaO required to ppt. K as CaCO<sub>3</sub>.

As x : K :: 56 : 162,  
x = 0.345 K.

Let Y = gms. HCl equivalent to K in titration.

Y : K :: 72.9 : 162.  
Y = 0.45 K.

By derivation as given in a previous paragraph  
x (83.3) = X, lb. lime per 1000 gal.

∴ X = (83.3) (0.345) K = 28.75 K lb. CaO required per 1000 U. S. gallons, but with a 100-cc. sample of water, Y = 0.45 K.

And Y must = 28.75 K cc. so that burette will read lb. per 1000 gallons.

Hence Y = 0.45 K gms. HCl existing in 28.75 K cc. of acid, or 1 cc. = 0.01565 gm. HCl.

This acid solution has been found too strong for use and one-fourth this strength has been arbitrarily adopted. If we make an HCl solution so that 1 cc.

$\frac{0.01565}{4} = 0.00391$  gm. HCl, then the equivalent of 1 cc. in CaO equals (0.00391) (56) ÷ 72.9 = 0.0030 gm. and the equivalent in soda ash of 1 cc. equals

<sup>1</sup> 83.3 (lb. in U. S. gal.) × 7000 (gr. in lb.) ÷ 1,000,000 = 0.0583.

$(0.00391)(106.1) \div 72.9 = 0.0057$  gm.  $\text{Na}_2\text{CO}_3$ , but if the molecular weight of  $\text{Na}_2\text{CO}_3$  were exactly equal to twice the molecular weight of  $\text{CaO}$ , then we should have found that 1 cc. of the  $\text{HCl} = 2(0.0030) = 0.0060$  gm.  $\text{Na}_2\text{CO}_3$  instead of 0.0057 gm.  $\text{Na}_2\text{CO}_3$ .

If 1 cc. of the  $\text{HCl} = 0.0060$  gm.  $\text{Na}_2\text{CO}_3$ , then 1 cc. of  $\text{HCl} = 0.00413$  gm.  $\text{HCl}$  instead of 0.00391 gm. Let us take an average,  $(0.00413 + 0.00391) \div 2 = 0.00402$  gm.  $\text{HCl}$  required to the cc.

Such a solution can be made by using 1 cc. of concentrated acid per 100 cc. of distilled water and adjusted by titration against standard  $\text{Na}_2\text{CO}_3$  solution.

We arrived at the calculated strength of this acid solution by assuming titration on a 100-cc. sample. With such a sample, therefore, 1 cc. of this acid is equivalent to  $\frac{1}{3}$  lb. of  $\text{CaO}$  or  $\frac{1}{3}$  lb. of  $\text{Na}_2\text{CO}_3$ . These are the simple multiples referred to above.

This solution of  $\text{HCl}$  is prepared at the central laboratory and carried with the field apparatus. In order to make the field tests, the operator is preferably equipped as follows:

1. One 2-liter bottle of standard  $\text{HCl}$  solution.
2. One 50-cc. burette.
3. One balance to weigh out 10-gm. samples.
4. One 100-cc. graduate.
5. Two funnels. Filter paper.
6. Two 200-cc. Erlenmeyer flasks.
7. One glass tube 20 in. long and suitable single hole stopper to fit the Erlenmeyer.
8. Two 200-cc. beakers.
9. One oil burner to heat solutions.
10. One pound of ammonium chloride.
11. Solutions of methyl orange and phenolphthalein indicators.
12. One small mortar and pestle.

The above equipment comprises the portable laboratory which the operator can carry from station to station for making tests on the individual machines. In making these tests there are two general possibilities in connection with the use of  $\text{CaO}$  and  $\text{Na}_2\text{CO}_3$  with the water to be softened. Theoretically the  $\text{CaO}$  should only be used to precipitate the  $\text{Ca}(\text{HCO}_3)_2$  as  $\text{CaCO}_3$ , leaving the calcium and magnesium sulphates to be precipitated as carbonates by the  $\text{Na}_2\text{CO}_3$ . However, in cold solution  $\text{Na}_2\text{CO}_3$  does not completely precipitate magnesium as  $\text{MgCO}_3$ , because of the formation of soluble magnesium bicarbonate. This may be prevented by introducing excess lime to the point of completely precipitating all the magnesium as hydrate and to form a protective alkalinity so as to avoid the possibility of magnesium bicarbonate formation. When this condition is established, the magnesium is completely precipitated in the cold by the  $\text{Na}_2\text{CO}_3$ . Obviously such a procedure is more expensive, because the excess  $\text{CaO}$  so used must be thrown out by using its equivalent of  $\text{Na}_2\text{CO}_3$ , so that for each  $\text{Mg}(\text{OH})_2$  precipitated one calcium ion goes into solution as sulphate. However, the additional cost incurred by this excessive use of  $\text{CaO}$  is small compared to the benefit derived from the more complete removal of magnesium from the boiler water. On this basis therefore the following procedure is set down:

As  $\text{Ca}(\text{HCO}_3)_2$  is alkaline to methyl orange until the following reaction is complete

Therefore—(a) Take 100 cc. raw water, add 2 drops of methyl orange. (b) Titrate cold = A cc. of standardized  $\text{HCl}$ .

We may divide A, cc. by 4 and find the pounds of chemically pure  $\text{CaO}$  required per 1000 gallons of raw water to precipitate all the  $\text{Ca}(\text{HCO}_3)_2$  as  $\text{CaCO}_3$ . But for the present, we note down A, cc. and divide by 2 to obtain the pounds per 1000 gallons of  $\text{CaO}$  required, which will be explained later.

Since 1 cc. of  $\text{HCl}$  solution equals  $(0.00402 \div 72.9) 56 = 0.00309$  gm.  $\text{CaO}$ , if it were possible, we might put 0.1545 gm. of chemically pure  $\text{CaO}$  into 100 cc. of distilled water and titrate the mixture with exactly 50 cc. of  $\text{HCl}$  solution. Further, we could multiply the amount used by 2 and read 100 per cent as the purity of  $\text{CaO}$ . Similarly we can put 0.1545 gm. of any lime into 100 cc. of distilled water, titrate and multiply the cc. used by 2 and get the per cent of  $\text{CaO}$  in the lime. Putting 0.1545 gm. into 100 cc. is the same as putting 10 gm. into 6470 cc., a procedure practicable in the field. However, as there is no distilled water to be had outside of the laboratory the 100 cc. of the raw water will react with the equivalent of A, cc. expressed as c.p.  $\text{CaO}$ . For each 100 cc. of the 6470 cc., therefore, this amount of c.p.  $\text{CaO}$  is precipitated as  $\text{CaCO}_3$ . Further we know that when we put this amount of lime into such water, some very insoluble  $\text{Mg}(\text{OH})_2$  is precipitated. Thus the simple addition of lime to the water, boiling, cooling and titrating with phenolphthalein does not usually give a sufficiently sharp end-point. For this reason, let us take about 150 cc. of this mixture, boil, cool and add  $\text{NH}_4\text{Cl}$ . Then any  $\text{Mg}(\text{OH})_2$  will go into solution as  $\text{MgCl}_2$  and yield an equivalent amount of  $\text{NH}_4\text{OH}$ . We can now filter this solution free from  $\text{CaCO}_3$  on the assumption that the boiling has rendered the  $\text{CaCO}_3$  crystalline and scarcely at all soluble in the  $\text{NH}_4\text{Cl}$  solution. Take 100 cc. of the filtrate, add 2 drops of methyl orange and titrate to get A, cc.

Put 10 gms. of lime into 6470 cc. of water and mix well.

Take about 150 cc. of well-agitated mixture into a flask (boil under condenser and cool).

Add  $\text{NH}_4\text{Cl}$  to the cold mixture in the flask.

Thoroughly agitate, settle for 15 minutes and filter cold.

Take 100 cc. of filtrate for titration which takes A, cc. of acid. Then:  $2(A_1 + A_2) =$  per cent of  $\text{CaO}$  in the lime.

This summation  $A_1 + A_2$  represents the number of cc. of acid that would have been used in the titration, were it possible to conduct the operation in distilled water. Note also that no distilled water was used in the manipulation.

If we had not added the  $\text{NH}_4\text{Cl}$  to the above mixture but had filtered the mixture at once, a titration of the filtrate would have revealed the  $\text{CaO}$  in solution, which had not been used either to precipitate  $\text{Ca}(\text{HCO}_3)_2$  as  $\text{CaCO}_3$  or  $\text{MgSO}_4$  as  $\text{Mg}(\text{OH})_2$ . Then since  $A_1 + A_2$  represents the total  $\text{CaO}$  added, we subtract  $A_2$ , the excess of  $\text{CaO}$  added, and divide by 4 to find the pounds of chemically pure  $\text{CaO}$  required per 1000 gallons of water treated. This is of course based on the assumption that there is sufficient volume of water used to dissolve all the  $\text{CaO}$  existing in the 10 gms. of lime added and that no precipitation of  $\text{CaO}$  occurs from atmospheric  $\text{CO}_2$  during the manipulation. These conditions do not always exist. Hence the value of total  $\text{CaO}$  required, found in this way, should merely be

regarded as a guide. Further it should be remembered that this is the extreme limit of the requirements for CaO. It is not necessary to use enough CaO to precipitate all the  $\text{MgSO}_4$ , as  $\text{MgOH}$ , it is only desirable to partially accomplish this, so as to have alkalinity enough to prevent the formation of magnesium bicarbonate. Therefore it is advisable to but slightly exceed the  $\frac{1}{2}A$  value for CaO. This condition for raw water is usually reached when  $2\frac{1}{2}A$  or  $\frac{1}{2}A$  lb. c.p. CaO per 1000 gallons are used. The value found at  $A_3$  is merely noted for a check on lime consumption.

Take about 150 cc. of well-agitated lime mixture.

Filter without addition of  $\text{NH}_4\text{Cl}$ .

Titrate 100 cc. of filtrate =  $A_3$  cc. HCl solution.

Then:  $(A_1 + A_2 - A_3) \div 4$  equals pounds per 1000 gallons of c.p. CaO required, subject to the minor variations mentioned above.

One cc. of the HCl solution equals  $(0.00402 \div 72.9) (106.1) = 0.00585$  gms.  $\text{Na}_2\text{CO}_3$ . If we put 0.2925 gms. c.p.  $\text{Na}_2\text{CO}_3$  (anhydrous) into 100 cc. of distilled water and titrate it using methyl orange as an indicator with exactly 50 cc. of the HCl solution, we could multiply the cc. of acid so used by two and prove the material to be 100 per cent. Similarly, when we add 0.2925 gm. of any soda ash to 100 cc. of distilled water or 10 gms. to 3420 cc. and titrate 100 cc. of the solution, we find the percentage of  $\text{Na}_2\text{CO}_3$  by multiplying the cc. used by two. Usually there is no distilled water in the field supplies but since 100 cc. of crude water is equivalent to  $A_1$  cc. of acid solution because of its bicarbonate alkalinity; hence, if the titration of this solution requires  $A_1$  cc. we can say  $2(A_1 - A_2)$  the per cent of  $\text{Na}_2\text{CO}_3$  in the soda ash. It should be noted that this solution of soda ash added to the raw water will cause a precipitation of all the calcium existing as  $\text{CaSO}_4$ , etc., and of at least part of the magnesium. The  $\text{Ca}(\text{HCO}_3)_2$  is not affected. If we agitate the mixture well and take a 100-cc. sample to which a pinch of  $\text{NH}_4\text{Cl}$  has been added to dissolve the  $\text{MgCO}_3$ , the  $\text{CaCO}_3$  precipitate is crystalline and alkaline to methyl orange. It is advisable to add the acid slowly near the end point so as not to exceed the  $\text{CaCO}_3$  equivalent.

Put 10 gms. of soda ash into 3420 cc. of water.

Agitate well and take 100 cc. of the mixture.

Add  $\text{NH}_4\text{Cl}$  to 100 cc. of mixture.

Add 2 drops of indicator and titrate, which takes  $A_1$  cc. of the acid solution.

Then:  $2(A_1 - A_2)$  equals the per cent of  $\text{Na}_2\text{CO}_3$  in the soda ash.

If 100 cc. of raw hard water were treated with a given weight of c.p. anhydrous  $\text{Na}_2\text{CO}_3$  and the solution evaporated to dryness, taken up in distilled water, filtered and titrated, we could determine the  $\text{Na}_2\text{CO}_3$  consumed in precipitating the calcium and magnesium sulphates, etc. The  $\text{Ca}(\text{HCO}_3)_2$  is decomposed and precipitated as  $\text{CaCO}_3$  by the evaporation. Such a process can not be conveniently carried out in the field. However, when the CaO is added to the 6470-cc. portion of the water, it precipitates  $\text{Ca}(\text{HCO}_3)_2$  as  $\text{CaCO}_3$  and  $\text{MgSO}_4$  as  $\text{Mg}(\text{OH})_2$ . For each equivalent of magnesium so precipitated, one of calcium goes into solution as sulphate. Therefore, when  $\text{Na}_2\text{CO}_3$  is subsequently added to this mixture, the same amount of  $\text{Na}_2\text{CO}_3$  is consumed to precipitate the newly formed  $\text{CaSO}_4$ , as would have been required to precipitate the original

$\text{MgSO}_4$ . As far as the total alkalinity of the filtrate is concerned, it is not important whether the  $\text{MgO}$  is changed to  $\text{MgCO}_3$  or not. If the carbonate precipitation is conducted in a solution containing any free alkali, then bicarbonate does not form, and the magnesium is completely precipitated in the cold. Also if to any solution containing CaO an excess of  $\text{Na}_2\text{CO}_3$  is added and the solution filtered, the total alkalinity of the filtrate is equal only to the alkalinity of the  $\text{Na}_2\text{CO}_3$  introduced, and the original alkalinity due to CaO remains on the filter paper as  $\text{CaCO}_3$ . On this basis then we can take 3420 cc. of the lime mixture already prepared, add 10 gms. of the same soda ash used at  $A_1$ , agitate well, settle, filter, and titrate 100 cc. to get  $A_3$  cc. Under these conditions the magnesium is completely precipitated as carbonate in the cold, due to the presence of the NaOH or CaO which prevents the formation of magnesium bicarbonate.  $\frac{1}{2}(A_1 - A_2 - A_3) =$  lb. of c.p.  $\text{Na}_2\text{CO}_3$  per 1000 gallons required for reacting with Ca and Mg sulphates.

Agitate lime mixture made at  $A_1$ .

Measure off 3420 cc. of this lime mixture and add 10 gms. soda.

Agitate well and settle.

Filter and titrate 100-cc. portions which equals  $A_3$  cc.

At this point we might mention that some prefer to describe water in terms of degrees of temporary and permanent hardness. As a basis for discussion we might define for ourselves one degree of hardness as 1 mg. per liter of  $\text{CaCO}_3$ . The degrees of temporary hardness are those dispelled by boiling or the parts per million of  $\text{Ca}(\text{HCO}_3)_2$ , expressed as  $\text{CaCO}_3$ . Then since we can theoretically express any salt by its chemical equivalent, weight of  $\text{CaCO}_3$ , by manipulation of the

relative molecular weights, we can say:  $\frac{120 \times 100}{4 \times 56} A_1 = 53.5 A_1$ , = degrees of temporary hardness, where 120 is the reciprocal of 0.00835, the number of which mg. per liter must be multiplied to give pounds per 1000 gallons, and 56 is the molecular weight of CaO and 100 of  $\text{CaCO}_3$ . Moreover, since the amount  $(A_1 - A_2 - A_3) \div 2$  found at  $A_3$  may be considered as the  $\text{Na}_2\text{CO}_3$  required to precipitate the Ca and Mg mineral acid salts and since we regard the molecular weight of  $\text{Na}_2\text{CO}_3$  as twice that of CaO we may write

$\frac{100 \times 120}{4 \times 56} (A_1 - A_2 - A_3) = 53.5 (A_1 - A_2 - A_3)$  = the calcium and magnesium mineral acid salts expressed as  $\text{CaCO}_3$  = degrees of permanent hardness. It may be urged that these degrees of hardness be determined by the use of a standard soap solution and calculation of softening reagents required made therefrom. Such determinations have not been found reliable nor anywhere near as extensive in the information conveyed as is required in this work.

As a further demonstration upon the action of the softening machines, we see from the following equations that reagents can be weighed in grams and put into 8.35 liters of water. The same conditions will obtain then as in the case of using pounds per 1000 gallons. Thus the operation can be observed on a small scale.

1 lb. per 1000 gal. = 453.6 gm. per 3785.4 liters =  
1 gm. per 8.35 liters.

Another set of tests may be made upon the machines in operation. Consider the liquid which issues from the lime tank. This is milk of lime emulsion and contains CaO in solution. Also CaO,  $\text{CaCO}_3$ , and  $\text{Mg}(\text{OH})_2$  are in suspension. It must be a milk of lime, not merely a solution, in order to convey in a small volume a sufficient amount of CaO for the entire volume of water under treatment. Such an amount is in excess of the solubility of CaO in the small volume of water passing through the lime tank. Hence what we want to know in such an emulsion is its actual content per 1000 gallons of  $\text{MgO}$  and CaO in solution and suspension. Here again we can use  $\text{NH}_4\text{Cl}$  under conditions as previously described. Thus we take about 150 cc. of this mixture, boil to render  $\text{CaCO}_3$  crystalline, cool, add  $\text{NH}_4\text{Cl}$ , agitate and settle. This will dissolve  $\text{Mg}(\text{OH})_2$ , and permit any CaO in suspension to go into solution. We can filter such a mixture, leave the  $\text{CaCO}_3$  on the paper and titrate 100 cc. of the filtrate which equals  $B_1$  cc. We know that  $B_1$  cc. includes  $\text{Mg}(\text{OH})_2$  precipitated by CaO but this makes no difference for it represents alkali nevertheless.

Take a 150-cc. sample of the emulsion issuing from lime tank. Boil, cool, add  $\text{NH}_4\text{Cl}$ , agitate and filter.

Titrate 100 cc. of filtrate to get  $B_1$  cc.

$B_1 \div 4 =$  pounds c.p. CaO issuing in each 1000 gallons that flows out of this tank.

It may be advisable to know the condition of the water as it completes its journey through the softening machines. A sample may be taken above the filters. The procedure is nearly the same as at  $A_1$ . Treat a 3420-cc. sample with a small amount of lime (2 gms.) to render alkaline and proceed as if it had no previous addition of  $\text{Na}_2\text{CO}_3$ . Carry through the determination exactly as if it were the  $A_1$  lime mixture. Filter the liquid after boiling under the reflux condenser as before and titrate 100 cc. which will give  $B_2$  cc. We know that at the time these tests are made the procedure of putting 10 gms. of soda into 3420 cc. of water introduces an equivalent of  $(A_1 - A_2)$  in terms of c.p.  $\text{Na}_2\text{CO}_3$ . If we titrate the liquid from this test and find it to be  $B_2$  cc. we can write:  $\frac{1}{2}(B_2 - A_1 + A_2) = \pm \text{lb. per 1000 gallons of c.p. Na}_2\text{CO}_3$ . The plus or minus sign in the result is important because: If  $B_2$  is greater than  $(A_1 - A_2)$  then the sign is plus and we know that there was free sodium carbonate in the solution at the time that test was made, and exactly as much as is expressed by the solution of the equation.

If  $B_2$  is less than  $(A_1 - A_2)$  then the sign is minus and we know that there was an insufficient amount of  $\text{Na}_2\text{CO}_3$  present to complete the precipitation of the alkaline earth salts by the exact amount shown by the solution of the equation.

Take 3420 cc. of water above filters, and add about 2 gm. of lime.

Add 10 gms. of soda ash on which  $(A_1 - A_2)$  has just been determined.

Agitate well and settle as with  $A_1$ .

Filter and titrate 100 cc. to get  $B_2$ .

Then,  $(B_2 - A_1 + A_2) \div 2 = \pm \text{lb. per 1000 gallons c.p. Na}_2\text{CO}_3$ .

If positive, lb. per 1000 gallons excess present.

If negative, lb. per 1000 gallons short.

This is an identical procedure as for  $B_1$  and is made upon the water storage tanks. It may often be possible

to make slight corrections by additional reagents even after the water has entered the storage tank. Though these methods may seem complicated and perhaps are somewhat theoretical, the practical directions as issued to the operator are simple and may be summarized as follows:

#### *Directions to operator*

$A_1$  Take 100 cc. raw water, add 2 drops of indicator. Titrate cold with HCl solution =  $A_1$  cc. ( $\frac{1}{2}A_1 =$  lb. per 1000 gal. c.p. CaO required. This figure divided by the per cent of CaO gives lb. per 1000 gallons crude lime required).

$A_2$  Put 10 gms. crude lime into 6470 cc. of water and agitate.

Take about 150 cc. of well-agitated mixture into a flask, boil and cool.

Add a small amount (2 grains) of  $\text{NH}_4\text{Cl}$  to the cold mixture in the flask.

Stir mixture in flask well and filter cold.

Titrate 100 cc. of filtrate in the cold with HCl solution =  $A_2$  cc.

Then:  $\frac{1}{2}(A_1 + A_2)$  per cent CaO in the crude lime.

$A_3$  Take about 150 cc. of the above well-agitated lime mixture.

Filter without addition of  $\text{NH}_4\text{Cl}$ .

Titrate 100 cc. of filtrate with HCl =  $A_3$  cc.

Then:  $(A_1 + A_2 - A_3) \div 4 =$  lb. per 1000 gal. c.p. CaO required by the water. (This figure divided by the per cent of CaO gives lb. per 1000 gallons of crude lime required, when the absolute limit of lime consumption is wanted.)

$A_4$  Put 10 gms. soda ash into 3420 cc. of water.

Agitate well and take 100 cc. of mixture.

Add a pinch of  $\text{NH}_4\text{Cl}$  to the 100-cc. mixture.

Titrate in the cold with HCl solution =  $A_4$  cc.

Then:  $2(A_4 - A_1) =$  per cent of  $\text{Na}_2\text{CO}_3$  in the soda ash.

$A_5$  Agitate lime mixture made at  $A_1$ .

Measure off 3420 cc. of this lime mixture and add 10 gms. soda ash.

Agitate well and settle.

Filter and titrate 100-cc. portions with HCl solution =  $A_5$  cc.

Then:  $(A_4 - A_1 - A_5) \div 2 =$  lb. per 1000 gallons c.p.  $\text{Na}_2\text{CO}_3$  required by the raw water. This figure divided by the per cent of  $\text{Na}_2\text{CO}_3$  found at  $A_4$  gives the lb. per 1000 gallons of crude soda ash required.

#### *Solutions from lime tank*

(a) Take 150 cc. of sample of emulsion issuing from lime tank.

(b) Boil, cool, add  $\text{NH}_4\text{Cl}$  and filter.

(c) Titrate 100 cc. of filtrate with HCl solution =  $B_1$ .

Then:  $\frac{1}{2}B_1 =$  lb. c.p. CaO issuing in each 1000 gallons out of this tank.

#### *Sample taken above the filters*

(a) Take 3420 cc. of water, add 10 gms. soda ash and about 2 gms. of lime. (This must be same soda ash used at  $A_4$ , etc.)

(b) Agitate well and settle mixture as for  $A_4$ .

(c) Filter and titrate 100 cc. of filtrate cold =  $B_2$ .

Then:  $(B_2 - A_1 + A_2) \div 2 = \pm \text{lb. per 1000 gal. c.p. Na}_2\text{CO}_3$ . + = excess, - = deficiency.

Potrerillos, Chile.

# Mobile Chlorine Water-Purification Plant

Trucks Equipped with Mechanical Filter, Chlorinating Apparatus and Testing Laboratory  
Sterilize Water for Troops

BY ROBERT K. TOMLIN, JR.

War Correspondent of Chemical & Metallurgical Engineering

FOR emergency filtration, sterilization and analysis of water supplied to American troops at the front in France, specially designed mobile plants, mounted on standard motor trucks, have been placed in service. The first outfits of this sort were sent to a division in an American sector early in June. They are the forerunners of others which, it is planned, will be used pretty generally by the American Expeditionary Forces for producing temporary supplies of potable water pending the creation of the more or less permanent "water points" which present military engineering practice has developed for the advance zones. While they embody no principles of water treatment which have not been employed for years past in the United States, the portable

plants are nevertheless unique in so far as sanitary engineering practice of the allied armies is concerned. They represent an ingenious adaptation of standard American methods of water purification, on a comparatively large scale, to the special needs of Army service, the features of the new outfits being mobility and such compactness in arrangement that a complete water purification plant and analytical laboratory are carried on the chassis of a 3-ton truck.

The details of the "Steri-Lab" truck are shown in the accompanying drawing and photographs. At the rear end is a gasoline-driven pump of the double-acting piston type with a rated capacity of 20 gal. per minute which may be operated against a pressure of 100 lb. per

Elevation  
SIDE ELEVATION AND PLAN SHOW DETAIL OF MOBILE WATER-PURIFICATION PLANT

square inch. It is equipped with 50 ft. of 2-in. hose, foot-valve and strainer. The pump delivers direct to a Roberts mechanical filter of the pressure type, a 30-in. diameter vertical tank mounted over the rear axle. This filter has a hand agitator and is fitted with an alum pot.

An alum storage bin is mounted over the right rear wheel of the truck.

There are at the present time three different types of these motor-truck plants. The first is known as the "Steri-Lab" and comprises a pump, a pressure filter, a

CORNER OF WATER ANALYSIS LABORATORY—PUMPING PLANT, PRESSURE FILTER AND DECOLORINATOR

chlorinating apparatus and a laboratory. The second, the "Chloro-Pumping" outfit, is like the first, except that it carries no pressure filter, and has a pump of greater capacity than the "Steri-Lab." The third is essentially a laboratory on wheels for the chemical and bacterial analysis of water. These mobile plants were designed and equipped by the Wallace & Tiernan Co., Inc., of New York, working in collaboration with officers of the Corps.

Chlorine gas is applied at the pump suction, and the dose generally is much heavier than that employed in ordinary municipal water-works practice. It may vary from 4.5 to as much as 10 parts per million. A contact period of from 10 to 15 minutes is afforded by cylindrical tanks mounted under the work bench of the laboratory compartment of the outfit. With such an intensive application of chlorine, which is adopted to insure absolute safety in the quality of the treated water, it will frequently be necessary to dechlorinate with a thiosulphate solution applied through an adjustable sight feed. The chlorine is carried in 105-lb. cylinders. To a large extent our water-supply sterilization will be carried on with chlorine obtained from the gas service of the American Expeditionary Forces.

The filtered and sterilized water passes either to a discharge valve, where it can be fed to tank carts or stationary storage, or it may be left in the contact tanks for storage there. These four tanks have a capacity of 30 gal. each, and are tested for a pressure of 100 lb. per square inch.

The forward part of the truck body is occupied by the testing laboratory. This room is completely inclosed, and provided with a door from the rear and wire-glass windows on the side. It is completely equipped as a water-testing laboratory, with working bench, wash sink, water under pressure through faucets, hot air sterilizer for sterilizing water, autoclave, etc.

This type of machine will be able to sterilize 1200 gal. of water per hour when operating through its full system. A bypass is provided around the filter, so that if a water supply is encountered which does not require filtration to remove turbidity and color, but simply chlorination to make the water bacteriologically safe, the capacity may be increased.

The second type of mobile plant, or "Chloro-Pumping" outfit, is carried on a 1½-ton instead of a 3-ton truck. Here there is no pressure filter. The pump has a capacity (40 gal. per minute) double that of the "Steri-Lab" machine. This outfit is designed for emergency work during an advance or a retreat where filtration may be dispensed with. The chlorinating and thiosulphate apparatus is of the same kind as that previously described.

The "laboratory," or third, type of truck is also carried on a 1½-ton chassis. It is fitted with the usual equipment for making chemical and bacteriological examinations of water. All racks and cases are felt-lined to prevent glass breakage. Water for laboratory use is contained in a tank fitted with a hand air pump to supply pressure. On this truck will be carried a bicycle for the use of the laboratory assistant in collecting samples.

### Domestic Chrome Ore Supply Satisfactory

The War Industries Board announces through Mr. Hugh W. Sanford, chief of the ferro-alloys section of the chemicals division, that the situation with regard to chrome ore in United States is well in hand.

## Washing in Filter Presses

By D. R. SPERRY

THOROUGH WASHING

THE most important and the most widely used method of washing employed in filter-presses is known as "thorough washing." This system of washing has also been called "every-other-plate system" from the fact that every other plate only has a wash inlet. "Back washing" is a term sometimes used because of the fact that the wash-water fills the space back of the cloths in contradistinction to simple washing where the wash-water enters between the cloths with the cake. "Through washing" has been used to denote this system probably from the incidence that the wash-water goes completely through the cake and both cloths. This term may also be a corruption of the word "thorough."

FIG. 1. CROSS-SECTION THROUGH RECESSED-PLATE FILTER-PRESS

Occasionally one hears the term "every-other-cock system," because in this system every other cock is closed.

### THOROUGH-WASHING IN RECESSED PLATES

In thorough-washing two different kinds of plates are used in each arrangement. The two kinds of plates are placed alternately in the filter press. The difference between the two plates lies in the fact that one has an inlet from the wash eye to both surfaces while the other has no inlet whatever from the wash eye to the interior. These plates are distinguished from each other by the terms "wash plate" and "non-washing plate" respectively. Fig. 1 is a cross-section through a recessed-plate filter-press. The upper cross-section passes through the feed channel while the lower passes through the wash channel.

The plates are clothed in the usual manner and placed in the filter press, first a non-washing plate, next a washing plate, and so on until the filter-press is com-

FIG. 2. PATH OF WATER IN THOROUGH-WASHING SYSTEM

pletely filled. In Fig. 1 the upper plate is a non-washing plate as there is no connection between the small upper-right-hand-corner eye and the interior of the plate. The lower is a washing plate because the small upper-right-hand eye has an inlet leading to both surfaces of the plate. In the thorough-washing system it should be borne in mind that the heads of a filter-press having an uneven number of plates are always different—one has an inlet from the washing channel and the other has not. Sometimes the stationary head is a wash-head, as shown in Fig. 1 (lower part), but it is just as likely to be a non-washing head depending upon the way the maker built the machine. In good practice, for reasons given later, filter-presses having an uneven number of plates have the stationary head, a washing-head, while if there is an uneven number of plates both heads are non-washing. However the heads may be, a non-washing plate must always come next to a washing-head as shown in Fig. 1, while a washing plate must always come in contact with a non-washing head. A head is non-washing if there is no connection between the wash eye and the surface of the head, while if there is such a connection as in Fig. 1, it is a washing-head. Filling of the filter-press is accomplished the same as was done in the plain recessed type, care being taken to see that the wash-inlet valve is closed and all cocks wide open. The material to be filtered, which is

pumped into the feed inlet, fills all the chambers formed by the plate recesses. As the liquid flows through the cloths bounding the chambers, the solids left behind fill the chamber completely, forming a cake. At this point the feed-inlet valve is closed and the pressure allowed to fall to zero. The cocks on all the washing plates and heads are then closed. The wash-water valve is then opened and the wash-water allowed to issue from the non-washing plate cocks. A study of Fig. 1 lower cross-section, shows that the wash-eyes form a continuous channel from one end of the filter-press to the other. When wash-water is forced into this channel it drops into only every other plate—the washing plates. In so doing it fills the space between the filter-base or cloth and the plate surface on both sides of the plate. The wash-water cannot pass directly out of the filter-press through the cocks because they are all closed on the washing plates. This being the case there is no way for the wash-water to get out except by passing through the cloth, through the solids and through the cloth on the non-washing plate. This is done with the result that the wash-water, after passing through both cloths and cake, emerges against the surface of the non-washing plate and passes downward and out through the cocks which purposely were left open on the non-washing plates.

In Fig. 2 an enlarged cross-section shows the path of the wash-water as used in the thorough-washing system. It will be noticed that since the cake through which the water must pass is twice the thickness through which the filtrate passed, the wash-water pressure must be greater than that used in filling the filter-press. Further reference to the proper washing pressure is given farther on. It should also be noted that the washing pressure is equal on both sides of the washing plates so that there is no danger of breaking plates by wash-water pressure. The pressure on both sides of the non-washing plates is also equal.

In Fig. 3 is shown a photograph of a washing plate of the recessed type. The picture is not large enough

FIG. 8. PATHS OF WASH-WATER IN EVEN AND UNEVEN NUMBER OF PLATES

to show sufficient detail to distinguish whether or not there is an inlet from the wash part to the plate surface. If this plate were a washing plate a close-up photograph would disclose a wash-inlet as shown in Fig. 4. If, however, it were a non-washing plate the wash part would appear without an inlet to the plate surface as shown in Fig. 5. A photograph of a thorough-washing filter-press with the cocks arranged ready for washing is shown in Fig. 6. The wash and feed inlets of a wooden-plate thorough-washing filter press are shown in Fig. 7.

#### WASHING AND NON-WASHING HEADS

In Fig. 8 are two diagrams showing roughly the path of wash-water through filter-presses having, in the upper diagram, an uneven number of plates, and in the lower an even number of plates. In the case of an uneven number of plates it can be seen that neither head is a washing-head provided the stationary head is non-washing. On the other hand if the stationary head is made a washing-head, then both heads must be washing-heads. As it is more expensive to make a washing-head than a non-washing head, the first arrangement is best.

In the case of an uneven number of plates it can be seen that one head is always a washing-head. As it is less expensive to make the stationary head a washing-head than to make the movable head washing (due to the fact that it forms the end of the wash-channel) it is proper for an uneven number of plates to have the stationary head a washing-head.

#### PRESSURE IN WASHING

Since the flow through a filter-cake is non-sinuuous,<sup>1</sup> in which the velocity of the liquid through the capillary paths varies directly as the pressure and inversely as the length of the channel (in this case thickness of cake), it would appear as though twice as much pressure would be required for the wash-water, since it flows through cake twice as thick as that passed through

by the filtrate, providing a flow of wash-water is desired at least as great as that of the filtrate. In actual practice only 10 to 20 per cent greater pressure is required on the wash-water, in most cases, to produce a reasonable flow. In filling a filter-press the pressure is allowed to build up gradually until it reaches a predetermined maximum. This maximum pressure, if distributed over a cake one-half the thickness of the chamber would produce a flow far greater than that last observed issuing from the filter-press cocks. In the later stages of filling, the opposing cake surfaces gradually come in contact with each other, usually first at the bottom of

the chamber and extending upward. The last bow, therefore, is from a restricted area and not from the large area covered by the wash-water; hence double the feeding pressure is not required on the wash-water to produce a good flow equal to that of the filtrate.

Batavia, Ill.

### Fuller's Earth in 1917

The production of fuller's earth in 1917, as shown by a report published by the United States Geological Survey, Department of the Interior, was 72,870 short tons, valued at the mine at \$776,632 or \$10.66 a ton. The increase over 1916 was 5048 tons, or 7 per cent, and \$69,681, or nearly 10 per cent. Since its beginning, in 1895, this industry has almost steadily increased until, in 1917, its output and the value and average price per ton of its product were the highest yet attained.

Fuller's earth is found in many States, but in 1917 it was mined and marketed in only six. Florida was the leading producer in 1917, having been credited with more than three-fourths of the total output and value. The other States, named in order of production, were Georgia, Texas, Massachusetts, Arkansas, and California. The Southern States produced 98 per cent of the domestic fuller's earth marketed in 1917. The imports of fuller's earth, 16,994 short tons, also increased in 1917, but they formed only 19 per cent of the consumption. A few of the prominent domestic producers are: Floridin Co., Quincy, Fla.; General Reduction Co., Dry Branch, Ga.; Lester Clay Co., Jacksonville, Fla.; John Olson, Benton, Ark.

### The Present Status of Electric Brass Melting

In the article on this subject published in our issue for Sept. 15, page 321, several errors appear which affect the continuity of text. Line 17, column 2, page 324, should be followed by the matter appearing on line 10, column 1, page 327, to line 35, column 1, page 328, inclusive, which in turn should be followed by the matter from line 18, column 2, page 324, to line 9, column 1, page 327.

## Recent Chemical and Metallurgical Patents

**Removing Suspended TNT from Spent Acid.**—In the general practice of the TNT plants, large storage tanks are used to hold the spent nitrating acid during a separation process, when the minute crystals of nitro toluol held in suspension in the acid gradually gather at the top. The specific density of the crystals approaches so nearly that of the acid that the buoyant force is slight and long standing is necessary before the crystals rise to the top. Mr. FREDERICK M. G. JOHNSON of Montreal, Canada, has received a patent on a rapid and safe process for making this separation: 1000 lb. of spent acid is introduced into a vessel, which is hermetically sealed, and a vacuum of 25 inches of mercury created in the vessel above the material. Immediately minute bubbles of gas commence to collect on the particles of TNT suspended in the acid; these bubbles are presumably due to the vapor pressure of the nitric acid being greater than its internal hydrostatic pressure, so that the vapors gather at all the liquid surfaces, and the particles are ballooned up at a rapid rate to the surface. The cleared acid is drawn off from the bottom of the vessel, and the ton sludge transferred to a smaller vessel and heated sufficiently to melt the TNT and cause it to separate completely from the acid contained. With this method of separation, much less acid is kept in idle storage. (July 9—2,71,575.)

**Production of Aluminium.**—GEORGE GIULINI of Italy notes that in the reduction of alumina with carbon in an electric furnace but little metal is formed, the bulk of it remaining as oxide, plus some carbide and nitride. He therefore proposes to effect the reduction in an electric furnace under high vacuum, thus removing the carbon monoxide as rapidly as formed and preventing it from reacting with the vaporous metal as follows:

The volatile metal is also quickly removed from the proximity of the reducing agent, and therefore carbides are not formed to a great extent. (1,257,995; Mar. 5, 1918.)

P. R. HERSHMAN of Chicago, Ill., patents the method of reducing alumina (especially in the presence of oxides such as  $\text{SiO}_2$ , which materially reduce its melting point) by carbides either introduced as such or formed in the furnace at temperatures below the reduction point of the alumina. He specifies that the proper mixture be pressed into such form as to make the resistor of an electric furnace, and that the gaseous products of the reaction be immediately withdrawn from the furnace. It is also necessary that the reaction be carried out in a reducing atmosphere, consisting of hydrogen or hydrocarbons, and that the resulting metal be tapped shortly after its formation. As an essential constituent of the resistor he adds small amounts of finely divided aluminium, copper or other heat-conducting metals. (1,273,220; assigned to the Mineral Products Co.; July 23, 1918.)

**Separating Nickel from Copper.**—JOSEPH DHAVERNAS of New Brunswick, New Jersey, notes that when nickel-copper mattes are roasted to form copper oxides, which latter are to be removed by leaching, the removal of copper is never complete unless the roasting is sufficient to oxidize considerable quantities of the nickel as well. He therefore specifies that the roasting shall be followed by a reducing fusion, converting the mixture of oxides and sulphides into a low-sulphur matte containing considerable metallic materials. Nickels may now be removed from this mass by leaching with a slightly acid copper solution, any excess of copper remaining in the liquid being removed by precipitation on metallic nickel. (1,273,465; assigned to United States Nickel Co.; July 23, 1918.)

JULIUS H. GILLIS of Toronto, Canada, electrolyzes a nickel-sulphate solution, using a cathode of nickel and an anode of nickel-copper alloy containing about 60 per cent of the former metal. During the flow of the current, pure nickel at first deposits on the cathode, while copper and nickel both enter solution at the anode, the nickel in larger proportion owing to "selective action" and to the preponderance of this metal in the alloy. Before the copper ions have been transported any considerable distance from the surface of the anode, the current is reversed. Nickel now goes into solution from the plate formerly the cathode, while spongy copper will largely be deposited on the erstwhile anode. The deposited copper falls off and collects in the bottom of the tank as a slime. It is found that the slime also carries iron and other formerly troublesome metallic impurities. A diaphragm may be used to prevent the slime contaminating the nickel deposit. With about ten alternations of current per minute, the reverse current being held for perhaps two seconds, a substantially copper-free nickel deposit may be obtained. (1,260,661; assigned to British American Nickel Corporation, Ltd.; Mar. 26, 1918.)

**Brick from Iron Blast Furnace Slag.**—J. B. SHAW of Alfred, N. Y., notes that while excellent paving brick is being made from English blast furnaces, an equivalent product has not yet been made in the United States. British practice consists in pouring molten slag into split metal molds, removing the red hot bricks when they have solidified sufficiently to be handled without deformation, and placing them into kilns where they cool and anneal slowly.

These bricks have a "stony" texture, while American bricks made in a similar manner are glassy and brittle. Composition of the slag probably has a great deal to do with these conditions, the British slag containing 26 per cent silica and 22 per cent alumina, while here the corresponding amounts are 34 and 14. In practice, American slags quickly solidify with a thin, tender skin, retaining a molten interior for a considerable period. To make successful brick the author specifies that the hot mass must be immersed in red hot sand, or some other hot medium which effectually excludes air and furnace gases, in such a manner that the heat from the packing and the molten interior reheats the chilled shell into a very viscous substance. Further cooling must now be arranged so that the exterior and interior of the mass shall cool at about the same rate, from 12 to 18 hours being required for proper annealing. (1,259,304; Mar. 12, 1918.)

## Synopsis of Recent Chemical and Metallurgical Literature

**Zirconium, its Alloys and Oxide.**—A paper followed by discussion on this rare element, especially its use as a refractory, was read at a meeting of the Birmingham (England) Metallurgical Society on March 14, 1918. Mr. LEOPOLD BRADFORD contributed the paper under discussion. It was remarked that the published material on zirconium and its compounds was so contradictory that it was difficult to know just what to believe. The metal has been recovered in amorphous, graphitic and crystalline form. The amorphous material, 97 per cent pure, produced by reducing potassium zirconio-fluoride with sodium in the presence of sodium chloride in a bomb furnace might be converted into metal 99.8 per cent pure by forming it into electrodes and striking an arc in an atmosphere of hydrogen at reduced pressure. The metal resembled white cast iron, had a specific gravity of 6.4, a specific heat of 0.0804, and a melting point of 1530 deg. C. Amorphous zirconium is a bad electrical conductor and oxidizes readily, while the crystalline variety oxidizes only at white heat and is not affected by strong acids. Aluminium-zirconium alloys are easily produced and have about the same properties as aluminium-titanium alloys. Ferro-zirconium is easily produced by the thermit process, and alloys containing up to 35 per cent had been used to some extent as scavengers. Alloys containing as high as 90 per cent have been marketed in America. It is rumored that such material is used in Germany for making armor some three times as resistant to penetration as the ordinary armor-plate, but the production of such ferro-alloys in quantity by the electric furnace was not thought to be commercially feasible. A self-hardening tool steel consisting of nickel, cobalt and chromium together with from 2 to 40 per cent of zirconium has been proposed.

The oxide, zirconia, was by far the most important compound, however, and has been largely used as a refractory. The properties of the material used in this way has been fully treated by H. C. MEYER in METALLURGICAL AND CHEMICAL ENGINEERING, Vol. 12, p. 791 and Vol. 13, p. 263. Dr. WALTER ROSENHAIN found that rather impure zirconia (75 per cent) had a very considerable shrinkage, apparently increasing with the temperature, and therefore making it imperative that the refractory should be burnt at a higher temperature than it was to resist during use. The refractory properties were increased enormously on purification, however. Though pure zirconia alone when molded for the production of refractory articles such as crucibles were apt to crack and crumble, even though heated up gradually, these drawbacks could be overcome by fusing the oxide in the electric arc furnace. Fused zirconia had a high thermal endurance, and was not affected when heated to redness and plunged into cold water, as its co-efficient of expansion—0.00000084—was extremely low, near to that of quartz glass. Its resistance to crushing stress was many times greater than that of quartz glass. Fused zirconia, therefore, appeared to be a refractory of exceptional value. Its hardness was between that of corundum and that of quartz. It had a specific

gravity of 5.89 and a porosity below 1 per cent. The melting point, as determined by PODSZUS, was 2,950 deg. C., but 0.5 per cent impurity reduced this by 100 deg.

**Electrolysis of Lock Valves at Panama.**—R. H. WHITEHEAD describes the corrosion taking place in the valves in the Panama Canal locks in the *Engineering News-Record*, June 27, 1918, V. 80, p. 1219. Fig. 1 shows the details of the valve chambers which have been giving the trouble. The valves control the flow of water in the 18-ft. culverts in the lock walls, and stop an opening 8 ft. wide by 18 ft. deep. During operation they are immersed in water more or less salty, although sea water is not necessary to set up the corrosive effects noted. It was thought that the valves would be replaced at intervals of ten years and that such replacement would be cheaper than to maintain protective coatings, but examination of several sets after less than two years' service shows very serious corrosion. Various metals are used in the construction—lead, babbitt, bronze, brass, steel and iron—of which steel is the most

FIG. 1.—DETAILS OF VALVE CHAMBER

electro-positive, with iron next in the list. The only attempt to nullify the galvanic action in the original installation was the placing of nine zinc electrodes in the lowest valves. Various paints and protective coatings were tested by coating a steel bar, immersing it in salt water with a dissimilar metal, and noting the curve traced with a recording millivoltmeter. None of the coatings showed a protection for longer than ten days except "bitumastic," which was accepted for the work. The bottom babbitt seat on which the valve rested had caused so much corrosion that it was necessary to plane off the bottom of the valve, and the babbitt was replaced with greenheart. The removable side steel strips had been so badly corroded that the leakage had increased to nine times normal; therefore they were replaced with lignum vitae. The lead used in caulking fixed irons and leading-in bolts was replaced by cement, zinc electrodes placed at the bottom of the bronze seals and all parts except rubbing surfaces coated with "bitumastic." Pipes were led to the bottom of the roller trains at the side of the valves, through which crude oil will be forced. This oil is expected to adhere to the uncoated rubbing-parts as it rises through the water, thus protecting them from corrosion. The roller train rods and valve stems which pass through water-tight stuffing boxes of brass are corroding at a rate which will require renewal in three years.

**Corindite, a New Refractory.**—ALEXANDRE BIGOT, Engineer to the French Ministry of Armaments, described a new aluminous refractory at the meeting of the British Ceramic Society held May 14, 1918. The material used in its manufacture is either the white, high silica bauxite, or the red, high iron bauxite so common in the south of France. The method of burning the material has been patented by the late M. Noel Leceesne, and consists in heating a mixture of bauxite and anthracite in a cupola using forced draft. During the process a considerable portion of the aluminium is reduced to the carbide, but this is reoxidized by the oxygen in the blast to alumina. At the end of the heat there remains a vesicular block fused in successive layers, containing a large number of small alumina crystals. After removal of magnetic metallics, this so-called "corindite" has the following analysis:

|                  | White bauxite fused. | Red bauxite fused. | Naxos emery. |
|------------------|----------------------|--------------------|--------------|
| Alumina          | 68.80                | 69.25              | 69.46        |
| Titanic oxide    | 3.85                 | 3.70               | ...          |
| Silica           | 21.40                | 3.00               | 2.41         |
| Iron oxide       | 5.25                 | 23.35              | 19.03        |
| Carbon           | 0.60                 | 0.50               | ...          |
| Lime             | ...                  | ...                | 2.18         |
| Loss on ignition | 0.10                 | 0.15               | ...          |
| Combined water   | ...                  | ...                | 5.47         |

Corindite cones start to melt at 1950 deg. C., being more refractory than the original bauxite. This is because most of the original ferrous iron has combined to form spinels,  $Al_2O_3 \cdot FeO$ . Binders containing lime and magnesia must be avoided, bauxite and kaolin being preferred. Hand made bricks contract 2 per cent in drying; machine made bricks dry with constant volume. During the normal burning to 1400 deg. C. there is no apparent shrinkage. Between 1700 and 1735 deg. C. bricks expand about 0.5 per cent, and from that point to 1850 they contract 3 per cent. These brick resist wear from three to four times as well as the best magnesite bricks, and a lining in a cement kiln lasts twice as long as one made from unfused bauxite. Corindite is attacked by slag and scoria in the same way as bauxite brick.

**The Swiss Kiln for Deadburning Magnesite.**—Two Swiss engineers, STEIGER and FREY, have erected a continuous vertical kiln for the dead-burning of magnesite on the island of Euboea, Greece, which has been in successful operation eighteen months. The output of the natural-draft kiln which the new kiln was designed to supplant was 4 tons of calcined material per day. The new kiln averages 14 tons per day, with a fuel consumption of 20 per cent, as compared to 35 per cent for the old. The new kiln requires 30 horsepower for driving the moving parts. It consists of a vertical chamber, lined with magnesite brick. Magnesite rock is automatically elevated to the top and charged continually through a bell. It gradually descends against hot gases, passing through the hottest zone, and thence into the cooling zone. The bottom of the shaft is closed by a flat conical casting, ribbed on top. Rotation of this casting at the rate of about two per hour delivers the finished material to the discharge chute and tends to break any lumps formed in the burning. Heating is effected by artificial gas delivered hot from a producer alongside and burned in air delivered under pressure. A temperature of 1700 deg. C. (approx-

imately that of the open hearth furnace) is effected when using a good grade of coal. The gases are drawn from the top by a suction fan, leaving the furnace at about 150 deg. C. The designer, E. Steiger, who described the installation at the May meeting of the British Ceramic Society, believes that its fuel economy may commend it to those who are calcining and burning various materials in the less efficient rotary kiln.

**Ray Materials for Silica Products.**—*The Iron and Coal Trades Review* for May 17, 1918, contains an article by A. BIGOT, Consulting Engineer to the French Ministry of Armaments and Munitions, on the raw materials entering into the manufacture of silica refractories. The author recommends close analytical studies of the quartzites used. He finds that a natural rock analyzing 95.95 per cent  $SiO_2$ , 2.65 per cent  $Al_2O_3$ , and 1.96 per cent  $FeO$  shows under the microscope that the quartz crystals were surrounded with amorphous matter. On very fine grinding (through 200 mesh) and water classification, the lighter fraction was found on analysis to have an alumina content of 7.6 per cent, which corresponds to a clay content of 22 per cent. This finest material is rather plastic, and is more fusible than the original rock. The grinding of such a quartzite would set free the entrapped clay, which in the presence of the fine quartz particles and a small amount of lime forms a plastic mass which begins to vitrify and contract at 1250 deg. C., enveloping the quartzite grains and forming the correct bond. Therefore, a study of the natural binding material contained in massive quartzites should be completed to obtain intelligent bonding.

A most important physical test consists in taking a piece of the quartzite weighing about 100 grams, heating it gradually to 1710 deg. C., holding it at that temperature for one hour, and cooling in the furnace. During this time the rock has reached its maximum expansion, and the appearance after the test gives much information. Rocks containing alkalis or an excess of alumina are fused, and are therefore unsuitable for use as a silicious refractory. Some remain compact, preserve their shape, but present a few cracks, or in other cases split into a number of fairly large pieces. If the pieces themselves are tough and compact and of moderate size they are suitable for use in refractories. If the rock breaks into very small pieces, or granulate as do certain sandstones, the friability of the grains renders them unfit for use. Many sandstones act perfectly until a temperature of 1600 deg. C. is passed, rapidly disintegrating at 1700 deg. Flints usually break into large, tough pieces, which would seem to be ideal for the manufacture of bricks, but as a matter of fact, they contain so little natural clayey bond as to give unsatisfactory results. The author believes that the perfection of microscopic technology will soon enable one to determine the cause of the variable expansion of similar quartzites, ranging from 9 to 15 per cent. Exposure to high temperature changes quartz into cristobalite and into tridymite, with increase in volume. At the same time, the crystals are traversed by microscopic cracks, the number and size of which may determine the total expansion of the rock.

## Quantitative Determination of Suspended Tarry Matter in Gas

By F. W. STEERE

THE problem of making quantitative determinations of the suspended matter carried by coal retort gases has in the past given no end of trouble. The writer has tried every scheme suggested in technical papers, but found them not sufficiently reliable or too complicated for practical use.

The problem was solved for our own work by developing a suggestion found in the 1909 "Wrinkles" of the American Gas Institute. The method was worked

has been drawn. The tar carried by the gas leaves a characteristic stain on the paper and the amount of it can be determined either by comparison with a standard paper, or much more accurately, by weighing the paper before and after taking the picture.

The construction of the tar camera is well shown in the illustration, Fig. 1. It is made entirely of aluminium—including the cock. Aluminium will not corrode or be affected by any of the constituents of the gas.

Where the gas is under pressure, it is only necessary to screw the tar camera into the pipe line or apparatus at the point to be tested. The outlet of the camera is connected to the test meter, or measuring bottles, with rubber tubing, Fig. 2.

When the gas is under vacuum, it is usually simplest to use aspirators. If standard aspirator bottles of one or one-half cu.ft. capacity are used, the test meter is not necessary as the gas is measured as it is drawn into the aspirator. These aspirator bottles can be used in place of the test meter for measuring the gas when it is under pressure, as is illustrated in Fig. 3.

In long series of tests where a great number of pictures are to be taken with the gas under vacuum, the best arrangement is to connect the tar camera through a test meter and then tap into a point in the system

FIG. 1. VIEW OF TAR CAMERA SHOWING TEST PAPER ENCLOSED BETWEEN CASSETS.

out for determining the quantity of tar carried by coal gas at the different stages of condensation, but has also been found equally valuable for determining the quantity of suspended matter carried by any gas or the atmosphere. We have called the apparatus a tar camera because of the colored stain left on the filter paper by the tar taken from the sample of the coal gas under test. The tar camera does not eliminate gas plant trouble, but it does furnish a simple means of detecting it and studying its causes. How much tar does your gas carry on entering the ammonia scrubber? How much tar does it carry into the purifier? How do you know whether your tar extractor is working up to standard? As vital as these questions are—the number of plants that regularly make these determinations is almost negligible.

In plants subject to naphthalene trouble, it is especially important that a close watch be kept on the quantity of light tars carried into the ammonia scrubber. These tars are saturated with naphthalene when they enter the ammonia scrubber and come in contact with the ammoniacal scrubbing liquor. Phenols are dissolved out of the tar by the ammonia, forming salts more soluble in water than the phenols. The phenols are very good solvents of naphthalene. The inevitable result, therefore, when phenols are dissolved out of the tar, is to supersaturate the gas with the naphthalene set free.

This is the reason that gas tested after the ammonia scrubber shows more naphthalene than the gas entering the scrubber. The answer is to keep the quantity of tar carried by the gas at this point—a minimum. As a further illustration of the many problems that may be studied by the tar camera, consider the increased life of the purifying sponge if it were not fouled with light tars.

### THE TAR CAMERA AND ITS APPLICATION

The tar camera is so called because it is used to take "tar pictures"—a tar picture being a piece of special white paper through which a certain amount of gas

FIG. 2. TAR CAMERA ATTACHED IN CIRCUIT WITH METER

which is under a greater vacuum than that being tested. In this way, pictures can be taken very rapidly and accurately.

The following points must be observed to insure accuracy:

Run trial pictures to determine the number of papers necessary—See paragraph "Number of Test Papers" below.

Blow out the connections after each test. If

naphthalene crystals appear on the paper, swab out the connections between each test.

The connection between the tar camera and the apparatus must be as short as possible, otherwise tar

several papers, in general, 70 per cent will be retained by the first paper, 25 per cent by the second, 3 per cent by the third, and 2 per cent by the fourth. But this is not, by any means, a hard and fast rule.

#### COLORIMETRIC METHOD OF ESTIMATING TAR CARRIED BY GAS

We have found that there is a rough relation with a given type of gas between the shade of tar stain and its weight. It is therefore possible to approximate the quantity of tar in the gas by comparing the stain with a standard.

Such a method depends largely on the observer's skill and ability in comparing the color shades. This method is not reliable when the amount of tar is so great that the paper no longer shows through. This condition is reached when a 1-cu.ft. sample contains about 50 milligrams of tar (equivalent to 110 lb. per million cubic feet).

If the amount of tar in the gas exceeds 100 lb. per million, then it is best to take a small sample of  $\frac{1}{2}$  cu.ft. or  $\frac{3}{4}$  cu.ft. for comparison. Also it is difficult to estimate extremely small amounts of tar by this method, except by taking larger samples (10 cu.ft.). Two milligrams of tar in a 1-cu.ft. sample (4.4 lb. per million) will leave a very light stain on the paper.

It must be remembered that retort gas, water gas and producer gas all give different stains, and the shade of the stain from any kind of gas will be largely influenced by the amount of free carbon it carries. Retort gas usually gives a light brown stain, turning darker after exposure to the air. Producer gas usually runs darker. Water gas tar may be very light on account of the presence of carburetting oil. Therefore the density

FIG. 3. TAR CAMERA IN CIRCUIT WITH ASPIRATOR

will be deposited in the connections and the results will be incorrect.

Always fully open the cock below the camera. If the gas is "wiredrawn" at this point, tar will be deposited after the cock and the test paper will not show the correct amount.

If the gas pressure is so great that the test papers burst on opening the cock full, then it will be necessary to place a small cock in the hose line leading to the test meter to limit the rate of flow. Always pinch the rubber tubing after the tar camera while the cock is being opened, then let the flow gradually increase.

The proper amount of gas to be used in a test is either one cubic foot or ten cubic feet. For very tarry gas (foul main, etc.) it may not be possible to get one cubic foot through the paper. Stop the test and read the meter when the flow has nearly stopped. For very clean gas (after purifiers, etc.) a better idea of the quantity of tar in the gas can be had by running a larger sample, but it is seldom necessary to run more than ten cubic feet.

#### NUMBER OF TEST PAPERS TO BE USED IN A TEST

Tar in a finely divided state will not all be stopped by the first paper, but will go on through and stain the next one and sometimes four or five layers. Two is the number usually used for routine work, but where the papers are to be weighed to determine accurately the amount of tar, not less than four should be used. Tests show that when the tar is light and penetrates

FIG. 4. RATE OF ABSORPTION OF MOISTURE BY PAPER

of the picture must be given consideration as well as the shade.

The amount of tar that is carried by gas will vary from about 800 lb. per million cu.ft. (5.6 grains per cu.ft.) or (262.4 milligrams per cu.ft.) down to clean

gas. We prefer to report tar in lb. per million cu.ft. This can be readily reduced to gallons per ton of coal.

Tar weighs approximately  $8\frac{1}{2}$  lb. per gallon. Retort gas runs approximately 10,000 cu.ft. per ton of coal carbonized. Producer gas runs approximately 120,000 cu.ft. per ton of coal. The weight of tar on a test paper is best reported in milligrams. If the tar in a 1-cu.ft. sample weighs 1 milligram, this is equivalent to 2.2 lb. per million cu.ft.

The colorimetric tests are not designed for accurate quantitative results—their value is rather roughly comparative. They will show any appreciable increase or decrease in the quantity of tar vapor present. They also indicate relatively the quality of the tar—which

FIG. 5. VARIATION OF MOISTURE WITH HUMIDITY

is an index to the retort house, producer, or generator operation. If an accurate quantitative determination is required, it can be made as described below.

#### GRAVIMETRIC DETERMINATION AND CORRECTIONS

For weighing test papers, nothing but a good chemical balance can be used. A 3-inch filter paper commonly weighs about 280 milligrams (0.01 oz.) and the tar collected on it often weighs as little as 1 milligram (0.000035 oz.), or even less. Even if a suitable balance is available, the correct weighing of a test paper is not by any means a simple procedure.

A dry 3-inch filter paper will absorb as much as 7 milligrams of moisture from the atmosphere. The amount of moisture absorbed depends upon the humidity of the air, and somewhat on the temperature. It will not absorb as much moisture after being saturated with tar as it will when clean, and therefore the error due to moisture cannot be corrected readily.

To show the great difficulty of getting the correct weight of a test paper, we give below several curves showing the gain in weight of a test paper taken from a dessicator and placed on the pan of the balance.

Fig. 4 shows a set of curves giving the rate of absorption of moisture by paper at 85 deg. F.; 77 per cent humidity. Curve 1 is for a clean paper 3 inches in diameter, weighing 260 milligrams when dry and clean. Curve 2 is for a 3-inch paper weighing 280 milligrams when dry, but loaded with 8 milligrams of tar. Curve 3 is for a 3-inch paper weighing 289 milligrams when dry, but loaded with 59 milligrams of tar. It will be seen that the clean paper increased  $5\frac{1}{2}$  milligrams during the first minute it was on the scale. Even if the weighing could be accomplished in  $\frac{1}{2}$  minute, this would mean an error amounting to 6 lb. of tar per million cubic feet—entirely too much to neglect.

The curve shows that in 8 to 10 minutes the weights become steady, but, unfortunately, the curves for the clean and tar-covered papers are not alike.

The curves in Fig. 5 shows how the weights are affected by humidity. Curve 1 is for the clean paper mentioned above. Curve 2 is for the paper treated with 8 milligrams of tar. Curve 3 is for the paper saturated with 59 milligrams of tar.

These curves show that the weight of a 3-inch paper changes about 1 milligram for each 7.3 per cent change in the humidity. As the humidity is likely to vary from 50 per cent up to 75 per cent during a single day, it will be seen how hopeless it would be to try to weigh test papers under atmospheric conditions.

The only accurate method of getting the correct weight is to do the weighing in a perfectly dry atmosphere. Drying out the interior of the balance case (with pans of calcium chloride) does not reduce the humidity much below 50 per cent and opening the door to put in a test paper or change weights, alters the humidity at once.

We have therefore found it necessary to provide other means of weighing test papers in a perfectly dry atmosphere, and experience has shown that this eliminates both of these errors and makes possible a very accurate result.

The Steere Engineering Co. is prepared to furnish tar cameras and test papers weighed according to its special methods. The weighed papers are put up in packages of 12 each, with the weight of each paper marked on the envelope. After taking the tar samples, the papers may be returned to it for accurate reweighing.

#### MECHANICAL AND ELECTROSTATIC DETARRING PROCESSES

The problem of completely separating the condensed tar vapors from coal gas has probably received more study and met with less success than any other step in the manufacture of artificial gas. All public utility gas plant operators are familiar with the "P. & A." tar extractor in its many modifications. Extractors working on the principle of the submersion washer are also very numerous. These types of apparatus, although a long way from being perfect, will, when properly operated, clean retort gas and carburetted water gas sufficiently for commercial operation.

On producer gas, however, these types of apparatus are entirely inadequate. The detarring of producer gas requires much more strenuous treatment. This fact is clearly proven in that the efforts of the past twenty-five years have brought on the market detarring apparatus of an entirely different type than that used

by retort gas plants. Producer gas detarring apparatus may be roughly divided into two classes—apparatus based on compression, wire drawing and sudden expansion, and apparatus of the rotary type, into which water is sprayed. None of these devices have proved satisfactory, and the power and maintenance charges make them almost prohibitive. It is evident to both operators and experimenters that these methods of attack are wrong.

Contrasted with these mechanical methods of tar extraction, we have approached the problem from an entirely new angle. The Steere electrical detarring process<sup>1</sup> consists in simply passing the gas through a zone of high-tension alternating current. The high-tension discharges completely precipitate all of the condensed tar vapor.

The great advantages of the electrical process are in its extreme simplicity and complete effectiveness. The power cost is practically negligible. This process also opens up a great many possibilities in the manufacture of coal gas which, with the old methods of condensation and detarring, do not exist.

Detroit, Mich.

## Pyrotechnic Smoke Signals

The Inventions Board, General Staff, Army War College, Washington, D. C., is desirous of receiving ideas and suggestions relative to the production of suitable material for smoke signals. The following information on the subject is given for the benefit of those who may wish to experiment along this line. Communications should be addressed to the Inventions Board as given above.

It is desired to secure, if possible, a suitable chemical substitute for red Saxony arsenic now used for the manufacture of yellow smoke signals. The characteristics of such a chemical are that it should produce the effect required, that it should be procurable in large quantities, and that it should be perfectly stable in combination with other chemicals, such as potassium chlorate. The effect desired is a rather deep orange yellow. There is no objection to the use of dyes should these give the effect required and be procurable in large quantities at a reasonable price.

A suitable formula for a red smoke signal is also a desideratum. The effect required is a pronounced and positive shade of red. As in the case of the yellow smoke signal, chemicals composing it should be readily procurable and should be stable. Since, however, the requirements for this signal are considerably smaller than for the yellow smoke signal a greater latitude may be allowed in selecting slightly less readily available and higher priced material for this signal.

The smoke signals outlined above are displayed from rockets, Very cartridges, Viven-Bessiere cartridges and 35 M/M cartridges. The rockets now used by our forces weigh about two pounds with an approximate length of eighteen inches. The V-B, Very cartridges and 35 M/M cartridges have an average length of about six inches with a diameter respectively of two inches, 25 M/M and 35 M/M. The V-B cartridges are thrown from the rifle grenade discharger, and the Very cartridges and 35 M/M cartridges from the 25 M/M signal pistols.

Should any person accredited by the Inventions Board become interested in the two pistols outlined above, this office would be very glad to give all the information in its possession.

It should be noted that "auramine" has already been tried as a dye for the yellow smoke signal and that "paratoner" has been used in the red smoke signal.

## Quicksilver Production in First Half of 1918

The production of quicksilver in the United States during the first half of 1918 was 17,576 flasks, according to F. L. Ransome, of the United States Geological Survey, Department of the Interior. The total production in 1917 was 35,954 flasks, and as one-half of this is 17,977 flasks, the quantity thus far produced this year falls short by 401 flasks of that which should have been produced if the output this year is to equal that of last. As quicksilver, if not absolutely essential to the conduct of war, is a metal for which it would be exceedingly difficult to find satisfactory substitutes in all of its uses, and as an output of 36,000 flasks would, it is estimated, be barely enough to meet the demands in this country in 1918, the shortage indicated by the returns for the first half of the year calls for energetic efforts by the producers, the consumers, and the Government to increase the supply of the metal and to curtail less essential uses. With the enlargement of our Army the demand for quicksilver is likely to be considerably greater in 1919 than in 1918, and the perfection of satisfactory detonators for high explosives that shall contain little or no mercury is one of the urgent problems of chemistry as applied to war.

The decline in production during the first half of 1918 was due chiefly to the shortage and the increased cost of labor and to the exhaustion or depletion of known ore bodies under the stimulus of high prices for the metal. The practice at some of the larger mines has been to devote nearly all energy to getting out ore and to postpone the underground exploration and development that are necessary to insure long-continued steady production. In the language of the miners, some of the mines have been "gutted," and considerable time will be needed to restore them to a condition of high productivity. On the other hand, the high price of quicksilver has not led as extensively as had been hoped to the reopening of old mines long idle, although there are some notable examples of this result, and, during the second half of the year, these reopened mines may make good the shortage. Quicksilver mining is full of uncertainties, and capitalists are slow to invest extensively in an undertaking whose future can be so little foreseen. There is opportunity here for patriotism to cast the deciding vote where the cold doctrine of chances might turn the investor to industries offering greater assurance of reward.

One of the notable achievements in the industry during the year has been the successful adaptation of the rotary cement kiln to quicksilver metallurgy. Eight of these furnaces are now or will soon be in operation in California, and they are expected to make an increase in production that may more than offset the falling off during the first half of the year.

<sup>1</sup>Proceedings of the American Gas Institute, 1914.

## Personal

MR. M. H. BARNES, formerly chemist for the Illinois Steel Co., Gary, Ind., is now division inspector for the Aluminum Company of America, Maryville, Tenn.

DR. W. M. BURTON has been elected president of the Standard Oil Co. of Indiana to succeed the late Lauren J. Drake. Dr. Burton was recently awarded the Walter Gibbs medal of the American Chemical Society in recognition of his original work in the chemistry of petroleum, and as the discoverer of the so-called Burton process for producing gasoline.

MR. NORMAN CARMICHAEL is serving as chairman of the United War Work Campaign at Phoenix, Arizona.

MR. W. W. COLEMAN and T. H. SYMINGTON have been appointed as special assistants to the Chief of Ordnance. Mr. Coleman will have charge of the production of cannon, carriages, and their appurtenances and accessories. Mr. Symington will have charge of artillery ammunition, metal components, but will have nothing to do with the loading plant operation.

MR. STUART CROASDALE announces the change of his business address to 730 Symes Building, Denver, Col., where he will continue his practice as consulting engineer in mining, metallurgy and industrial chemistry.

DR. RUDOLF GAHL has opened a consulting office in the First National Bank Building, Denver, Col., where he will continue to specialize in hydrometallurgy of copper ores, the design of new plants and the solution of operating problems in copper mills. Dr. Gahl was formerly connected with an Arizona copper company.

MR. H. C. PARMELEE, Editor of CHEMICAL AND METALLURGICAL ENGINEERING, has gone abroad on invitation of the British Government to visit England and France. He is one of a party of fifteen editors of business magazines who will be the guests of the British Government for about two months, returning to the United States late in December. The purpose of the trip is to facilitate the interchange of thought and opinion between the allied nations.

## Obituary

MR. EDWARD J. DITTUS, Denver, Col., died at his home Oct. 11, 1918, of pneumonia, following an attack of influenza. Mr. Dittus was a graduate of the Colorado School of Mines and for several years after his graduation was assistant in the department of metallurgy at Golden. Recently he had been employed on potash production at Alliance, Neb., where he was taken sick. He is survived by a wife and child.

DR. ERNEST G. GENOUD died on Oct. 12, 1918, of pneumonia following an attack of influenza. He was born Feb. 23, 1889, graduated from the Massachusetts Institute of Technology, 1908, studied at Charlottenburg and Berlin, achieving his doctorate Jan. 15, 1911. He addressed himself more particularly to processes of fermentation and to special researches in regard to yeasts and other micro-organisms. For several years he had been engaged in technological research in the laboratory of Arthur D. Little, Inc., Cambridge, Mass. An article by him on "The Use of Micro-Organisms in Chemical Industry" appeared in our issue of Oct. 15.

PROFESSOR F. P. TREADWELL of Zürich, Switzerland, died suddenly of heart disease on June 25, 1918. Professor Treadwell was born at Portsmouth, N. H., in 1857. In the early seventies he attended school at Heidelberg, and later was lecture assistant there from 1878 to 1881 under Bunsen. His subsequent professional service was in the Eidgenössische Polytechnicum in Zürich. His excellent textbooks on chemistry are widely used and his loss will be felt among chemists.

## Current Market Reports

### The Non-Ferrous Metal Market

**Tuesday, Oct. 22.**—Due to the control of the prices of metals by the War Industries Board, the market has generally reflected none of the varying political conditions due to peace talk and has great stability.

**Aluminum.**—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminum, 18 ga. and heavier, 42c.; powdered aluminum, 100 mesh, 70c.

**Antimony.**—There seems to be an overproduction of antimony and prices are tending to decline in spite of the closing down of the French North African mines. Small quantities range from 13½c. to 13¾c. per pound.

**Chrome.**—Western production is now in slight excess of demand. The nominal quotation for 40 per cent ore is \$140 per unit, while 50 per cent ore is bringing \$170.

**Copper.**—The price of \$520 per ton for car load lots and 27.3c. per pound for small quantities is expected to be continued for another period at the conference to be held on Oct. 25 in Washington.

|                                 |     |        |          |
|---------------------------------|-----|--------|----------|
| Copper sheets, hot rolled.....  | lb. | \$0.36 | —\$0.37½ |
| Copper sheets, cold rolled..... | lb. | .37    | — .38    |
| Copper bottoms.....             | lb. | .44    | — .45½   |
| Copper rods.....                | lb. | .36    | — .37    |
| Copper wire.....                | lb. | .29½   | — .30    |
| High brass wire.....            | lb. | .28½   | — .29    |
| High brass sheets.....          | lb. | .28    | — .28½   |
| High brass rods.....            | lb. | .26½   | — .28    |
| Low brass wire.....             | lb. | .32½   | — .34    |
| Low brass sheets.....           | lb. | .32½   | — .34    |
| Low brass rods.....             | lb. | .32½   | — .34    |
| Brazed brass tubing.....        | lb. | .35    | — .36    |
| Brazed bronze tubing.....       | lb. | .42½   | — .43    |
| Seamless copper tubing.....     | lb. | .41    | — .42    |
| Seamless brass tubing.....      | lb. | .45    | — .46    |
| Seamless bronze tubing.....     | lb. | .47½   | — .49    |
| Bronze (gold) powder.....       | lb. | 1.00   | — 1.75   |

**Lead.**—The lead market is limited by selling restrictions, the supply being allocated by the Lead Committee. In car load lots at East St. Louis, the price is \$155 per ton. In New York, all speculative and traders' lead has disappeared. The Lead Committee apportions lead at 8.05c. to legitimate consumers.

**Manganese.**—The scale prices on page 629 of CHEMICAL & METALLURGICAL ENGINEERING, June 15, prevail; the highest price per unit being \$1.35.

**Silver.**—The Government price of \$1.01½ is hoped to promote production.

**Tin.**—The Tin Committee of the American Iron and Steel Institute has not yet announced the official price on tin. No doubt an understanding will have to be had with the producers before a final statement can be made public and as they are all in distant foreign countries, considerable time will elapse in intercommunication. During the first two weeks of this month about 1700 tons were imported. The price is about 78c. per lb. and is expected to decline.

**Tungsten.**—The Western producers of scheelite are reluctant in offering at \$26 per unit. High grade wolframite is bringing \$25. Off-grade ores vary from \$20 to \$24.

**Zinc.**—Spelter is tending to decline slightly. East St. Louis is quoting \$173 per ton for October delivery and \$170 for November and December. New York spot is 8.85c. to 9c. per lb.; sheet zinc, 15c., and zinc dust (300 mesh), 16c. per lb. in 1600-lb. casks.

### OTHER METALS

### The Iron and Steel Market

While the actual reports are not available, production of pig iron during October is believed to have been at a slightly better rate than the greatly improved rate shown for September, while production of steel is believed to have been

at about the September rate. The actual tonnage will show an increase, on account of October having 27 working days against 25 for September. The epidemic of Spanish influenza has affected the working forces at many plants, while others have practically escaped. The highest percentage of idleness was shown at the Duquesne Steel Works, where for some time about 750 men, or about 15 per cent. of the regular working force of 5100 men, were off, chiefly on account of the epidemic. At the various plants affected production was curtailed to a much less extent than would have been expected from the number of men absent. At many plants inoculation has been general for both office and mill forces. Company physicians have great confidence in the serum used. It may be interesting to note that some steel works physicians insist that autopsies they have witnessed prove that what has been diagnosed as pneumonia accompanying Spanish influenza is something altogether different, the lungs being attacked by ulcers, and not by the formation of fibrine in the blood, as in true pneumonia.

#### WAR REQUIREMENTS

Practically coincident with the German peace drive, there has been an increased demand for steel in France, both from our Allies and from General Pershing direct. The rate of advance of the Allied arms, it appears, measures the volume of many classes of steel required, particularly railroad material. While the consumption of shells does not appear from news despatches at the front to be particularly large at this time, there is pressure for more shell steel, and this despite the fact that the forge shops appear to have run somewhat ahead of the machining operations.

New practices are being introduced as to the distribution of steel to shipyards, the object being to insure a larger supply of the descriptions of steel most needed by certain yards without increasing the total production of ship steel. All comparisons that can be made from information generally available indicate that much more steel has been shipped for account of shipbuilding than has actually appeared in hulls. A reservoir of steel between mills and shipways is very desirable, but the steel needs to be properly spread, an excess of steel at one yard being of no help to another yard that may be short.

The oil pipe line across Scotland, news of which became public through an interview of Franklin D. Roosevelt, assistant secretary of the Navy, was laid with pipe furnished by American mills several months ago, though there was no publication of the matter at the time. The order involved about 60 miles of 8-inch pipe, about 4000 net tons. The object of the line is to make it unnecessary for oil tankers to make the long and somewhat dangerous trip around Scotland. A much larger project is the 300-mile oil line of 12-inch pipe in Texas, orders for which have just been distributed to mills after a lengthy consideration of the subject. About 40,000 net tons is involved. The leading interest was allotted 175 miles, the remaining 125 miles being distributed to several independents.

#### DISTRIBUTION REGULATIONS

Important rulings have been made as to "reflected priority," a matter that had been differently interpreted in various quarters in the trade. The regulations providing "automatic priority" were promulgated late in July, under date of July 1. Orders for various named purposes are given their respective grades of priority. Material for building vessels for the Fleet Corporation, for instance, is given A-5 priority. The shipyards, therefore, can attach A-5 priority to the orders they give for material. The question was whether those from whom they bought could in turn attach A-5 priority to the orders they gave, for material to be used in filling the shipyard's orders, and through how many links such a chain could extend. The general ruling is now made "priority can be reflected but once," whereas previously the view had been entertained and followed in some quarters that priority could continue through several links. For a concrete illustration, under former practice a rod mill might recognize as A-5 priority the order of a rivet maker engaged in supplying a shipyard, whereas under the new regulations the rivet maker

cannot secure automatic priority for his rods, but must apply for an individual priority. Fears are entertained that so many priority orders will now have to be secured as to delay their issuance, also that the mills will receive many small orders, instead of a few large orders, for rods, merchant mill products, etc., and have difficulty in making up convenient rolling schedules.

After long consideration of the subject of limiting the production of the smaller sizes of standard steel pipe, the War Industries Board has decided to curtail the output of butt weld pipe as a class, and has indicated to each pipe mill the tonnage of steel that can be used for butt weld pipe during November and December. The trade estimates that the regulation will reduce the output of butt weld pipe by about 30 per cent. Under normal conditions standard steel pipe is made from 3-inch downward in butt weld, while 2, 2½ and 3-inch sizes in oil country goods are made by the lap weld process. A part or all of the steel thus saved will pass into oil country goods, stimulating their production, this being one of the objects sought by the new regulation.

The various agreements that have been made from time to time in the past few weeks between the Food Administration and the packers of nonperishable food products in tin cans, whereby certain sizes of packages have been eliminated and the packing of certain products has been curtailed, have been arranged into one comprehensive schedule and distributed to the tin plate mills. Up to date the manufacture of tin plate has been confined to the filling of Government orders and the supplying of tin plate to packers of food products. Indications are that arrangements will be made with a number of packers of products other than food whereby they will limit their operations and will thereupon be allowed to buy and use tin plate. By the order of September 6 the tin plate mills were required to operate during the last three months of the year at not over 70 per cent. of their rate in the last quarter of 1917, but under the regulations as to tin plate consumption the permitted consumption fell far short of absorbing a 70 per cent. production. The prospect now is that enough consumption will be permitted to furnish a market for nearly a 70 per cent. output.

#### The Chemical Market

**COAL TAR PRODUCTS:**—The position of most intermediates has undergone no material change; during the interval, however, in view of the fact that only a few of the items were subject to a pressing demand, stocks on the whole have not accumulated to such an extent that a surplus is on hand. This condition is due mainly to the toluol situation, which is no easier, and other normal causes that are prevailing. The demand for benzol has been sufficient to take the stock off the market, that has been in evidence for some time, and among the more important crudes, phenol is still in pronounced demand, both in the local market and for export purposes. Paranitriline has evolved to an easier position in the market, and para amidophenol is noticeably scarce, both the base and hydrochloride products.

**Phenol:**—The market rules very firm and a decided pressing demand has developed in the local market, though interest in the product for export purposes is still very pronounced. However trading in this direction is considerably curtailed through the difficulty in obtaining export licenses. Prices are subject to no material change, for either that which has been manufactured prior to August 20, or the more recent product.

**Benzol:**—The lack of buying interest that has been prevailing for some time in this market is no longer in evidence, and while trading is of no important volume, there is sufficient business passing at present to take the slack off the market. For material in tank cars, prices are subject to no change while in certain directions a fractional increase was noticed for material in drums.

**Dinitrochlorbenzol:**—Quotations generally received would indicate the position of this item is very firm. Stocks, however, are by no means liberal, though they are of sufficient quantity to take care of the current demand.

**Monochlorbenzol:**—The item is one of the intermediates which is more or less neglected, and cheap offerings fre-

quently appear on the market. Large factors, however, are not disposed to shade prices to force business.

**Benidine:**—There is no pronounced volume of business reported in the local market and the most noticeable buying interest is for export purposes. The base material and the sulphate are subject to no change in prices, throughout the market.

**Para Amidophenol:**—A number of factors in this line state they are sold up until the latter part of November. However, fair quantities of the material are available for immediate shipment in spite of the persistent demand for both the base and H. C. L. products. Prices in most directions have been advanced from 25c. to 50c.

**Paranitraniline:**—The stringent situation that has confronted the consuming trade for some time appears to be easing up, though stocks are not reported in liberal supply. During the past week some cheap offerings appeared on the market, and in a few directions prices have declined from 5c. to 10c.

**Paranitrotoluol:**—Users of this product at the moment are seemingly experiencing some difficulty in supplying their wants, owing to the fact that most manufacturers are in a sold up condition, and offerings of the material that appear in the resale market are sold at rather high prices.

**Benzoate of Soda:**—A peculiar situation continues to exist in this market; talk is rather bullish from most directions and the active trading in the item appears to be mainly between dealers, as there is apparently no pressure on the part of consumers in the market. Therefore it is difficult to actually determine the market situation of either the acid or the soda. A variation of prices is heard, with weak holders appearing frequently and playing havoc with the market.

**Aniline Oil:**—Some factors are completely sold up for a period, but from certain sources available stocks are fully in accordance with the consumption requirements. There is a very steady demand reported, but prices are quotably unchanged.

**H. Acid:**—Production is centered to a few hands, who report that they are all sold and the small lots that appear in the resale market seem to originate considerable interest. Manufacturers are apparently reticent about quoting on material for early future shipment. Quotations generally heard are virtually nominal, in the absence of real business.

**Saccharines:**—There are now many conflicting rumors with regard to the general situation of this market, but as near as it is possible to determine the condition, it is generally conceded in most quarters that its entire position is weakening from day to day. Sales that were consummated are closed at some low levels and offerings of the product are made at prices said to be very low.

**Dinitrophenol:**—Inquiry for this item has been very good, but material for immediate delivery is said to be scarce and quite difficult to locate, in the open market. Large factors of production are devoting their entire energies for government requirement and therefore there is no encouragement offered for civilian consumption. Offerings of the material, on contract, are subject to no change.

**Diethylaniline:**—The production of this material is not in such quantities so as to accumulate a surplus in stocks. While trading is not very strong, the volume of business passing is sufficient to keep the market scarce of spot material. Prices are quotably unchanged and remain at firm levels.

**HEAVY CHEMICALS:**—The prevailing conditions, such as peace talk, Spanish influenza and liberty loan drives, have apparently been the factors for the continued lull in the market during the past two weeks. Citric acid, which under normal conditions, is seldom of any particular interest, has developed the feature of the market during the week. Soda ash maintains a firm position and under the lack of interest that has continued for some time; in caustic soda some of the more important factors are closely observing the market, but feel that a weakening position is likely to develop. Calcium carbide is subject to a heavy call and sodium sulphide is in firm demand. There developed a fair call for silicate

of soda, but stocks of both the latter items are reported to be meager.

**Soda Ash:**—Dense material in the various packing is none too liberal in supply, though a strong demand is noted for western shipment. The position of the light product in barrels appears to be somewhat easier and offerings of single bags are in fairly good quantities. Trading during the past week was rather inactive and among the more important sales noted was several cars of single bag material at \$2.65 ex-warehouse and sales were consummated for barrel material \$3.20 ex-warehouse. Offerings at the close were somewhat easier and single bags were quoted at \$2.65 to \$2.70 ex-warehouse and ex-dock and in Painsville material was held at \$2.70 with some middle west shipments quoted at \$2.60. The double bag situation was more restricted in offerings and lots which appeared on the market were held at \$3.25 works. Barrel material was available in New York at \$3.20 and in Chicago quotations ranged from \$3.05 to \$3.10, while in St. Louis the same quotation was heard.

**Bleaching Powder:**—A very serious situation is confronting the consuming trade at the moment and quantities of this material are becoming more and more difficult to obtain. Some factors are quoting 6½c. and buyers of fresh goods are seemingly obliged to meet these prices to supply their pressing needs.

**Caustic Soda:**—The situation of this market is causing considerable comment and in spite of the unusually quiet conditions that have been prevailing, stocks were none too free and the undertone was rather firm up to the latter part of the week when shipments were in excess of the purchasing, and from all appearances the market has seemingly developed a somewhat weaker position. Prices at the close show a downward tendency from \$4.45 to \$4.40 ex-warehouse and from works quotations generally went from \$4.40 to \$4.35. The ground product maintained a firmer position with quotations from the more important factors, ranging from \$5.25 to \$5.50 ex-warehouse.

**Oxalic Acid:**—No unusual activity is noted at the moment, in this market. However trading is steady through routine channels and supplies are reported to be fully in accordance with the consuming requirements. Prices remain at the former firm levels ranging from 40c. to 45c. according to seller.

**Citric Acid:**—There is no question that this item featured the market with a steady and persistent demand throughout the week, due, it is reported, to the extensive use of the product in the present prevailing epidemic. The steady buying pressure has depleted stocks to a very noticeable extent, and prices therefore have advanced from 85c. to \$1.06 at the close, with buyers unable to cover at the latter figure in many instances.

**Magnesia Calcined:**—The light technical product is reported to be in rather scant supply and quotations from several directions are virtually nominal in the absence of firm offerings. However, where small lots of this particular grade are available, prices have been advanced from 70c. to 75c.

**Calcium Carbide:**—A very firm market is prevailing for this item, but spot stocks are in very limited quantities; lots which appear on the resale market are seemingly the only material available. Producers are not offering owing to their sold up condition and there is no encouragement offered when the situation of the product may be somewhat easier. There is a variation of prices prevailing, ranging from 17c. to 19½c. per pound, in drums crated for export.

**Bicarbonate of Soda:**—Prices are steadily soaring for this product which is apparently becoming more scarce from day to day. Occasional lots which appear on the market seemingly create considerable interest, and at the close sales were consummated at from 3½c. to 4c. per pound, which is regarded a high mark for the product.

**Bichromate of Soda:**—The position of this item in the market is gradually weakening and prices are steadily declining, fractionally, from day to day. Quotations at the latter end of the week ranged from 21½c. to 22c. per pound, though in some directions sales were made as low as 21c.

Financial, Construction and Manufacturers' News

## Construction and Operation

### Alabama

**ASHLAND**—The Dixie Graphite Co., 407 Jefferson Bank Building will build a mill on its graphite property here having a capacity of 200 tons per day. J. R. Malaney, in charge.

**BIRMINGHAM**—The Welded Products Co., 303 American Trust Building, has awarded the contract for the construction of a 90 x 225 ft. acetylene welding plant to the Smallman-Brice Construction Co., American Trade Building.

### Arkansas

**FORT SMITH**—The Missouri-Arkansas Oxygen Co., c/o Best-Clymer Manufacturing Co., will install a hydrogen plant in connection with its proposed oxygen plant.

### California

**GIANT**—Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of a TNT plant located near the nitric acid plant of the Giant Powder Co., to Grant, Smith & Co., Henry Bldg., Seattle, Wash. Estimated cost, \$1,435,000.

**MANTECA**—The city will build a sewerage system, outfall sewer and disposal plant. Estimated cost, \$42,000.

### Colorado

**SILVER CLIFF**—The Buffalo Hunter M. M. & D. Co. will build a concentration, roasting and cyaniding plant at its Mn-Ag open pit mine having a capacity of 400,000 tons per year and is in the market for crushers, Wilfley tables, gas producers, tube mills, Dorr agitators, steam shovels, track cars, engines, boilers and pipe. Estimated cost, \$150,000. Captain L. D. Miller, superintendent.

### District of Columbia

**WASHINGTON**—Bids will be received at the office of the General Purchasing Officer, Panama Canal, until November 13 for furnishing ferro-manganese, carbon bisulphide, calcium chloride, wax, sulphuric acid, ethyl alcohol, pitch, glue, fire clay, graphite, enamel, white zinc, red oxide of mercury, shellac, etc.

### Florida

**MIAMI**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will receive bids until Nov. 4 for the construction of a reclaiming building and septic tank. Specification No. 3549. Estimated cost, \$20,000.

### Illinois

**FRANKFORT**—The Elgin, Joliet & Eastern Railway Co. has awarded the contract for the construction of a water softening plant here to William Graver, 4809 Todd Ave., Chicago. A. Montzheimer, Joliet, chief engineer.

**GREAT LAKES**—The Bureau of Supplies & Accounts, Navy Department, Washington, D. C., will alter and build additions to its sewage disposal plant. Estimated cost, \$13,000.

**MOUNT CARMEL**—A Lieberman and Lewis Dumes will build a fertilizer plant near here. Estimated cost, \$25,000.

**SPAUDLING**—The Elgin, Joliet & Eastern Railway has awarded the contract for the construction of a water softening plant here, to William Graver, 4809 Todd Ave., Chicago. A. Montzheimer, Joliet, chief engineer.

### Iowa

**FAIRPORT**—The Commissioner of Fisheries, Department of Commerce, Washington, D. C., will build a laboratory building at the biological station here.

### Kansas

**FORT SCOTT**—The city will build dam and filtration plant. Estimated cost, \$82,000. Black & Veatch, engineers Interstate Building, Kansas City, Mo., preparing plans.

**GALENA**—The City will build a filtration plant. Estimated cost, \$100,000. Burns & McDonnell, engineers, Interstate Building, Kansas City, Mo., preparing plans.

### Louisiana

**NEW ORLEANS**—The Jackson Brewing Co. will remodel and convert its building into a plant for dehydrating vegetables, etc., also the manufacturing of alcohol and syrup.

### Maryland

**INDIAN HEAD**—The Bureau of Yards & Docks, Navy Department, Wash., D. C., will build a laboratory building here. Specification No. 3203. Estimated cost, \$20,000.

**MONKTON**—The Monkton Roller Co., Inc., has awarded the contract for the construction of a roller mills plant, to E. H. Mosher, 427 Munsey Building, Baltimore. Project includes 32 x 72 ft. main mill, 20 x 45 ft. corn mill and hydro electric plant, also equipment for same. Estimated cost, \$134,000.

### Massachusetts

**LEE**—The Smith Paper Co. has awarded the contract for the erection of a three-story, 90 x 100 ft. concrete and brick paper mill addition, to the Lynch Brick Construction Co., 205 High St., Holyoke. Estimated cost, \$60,000.

**WORCESTER**—The Wyman-Gordon Co., 105 Madison St., has awarded the contract for the construction of an additional story to its laboratory on Gold St. to E. J. Cross Co., 82 Foster St.

### Michigan

**DETROIT**—The Cummings & Moore Graphite Co., 672 Water St., will build a three-story, 133 x 135 ft. grinding room addition. Stahl & Kinsey, 117 West Ford St., architect, taking bids.

**GRAND RAPIDS**—The Grand Rapids Brass Co. will build a three story addition to its plant at Scribner Ave. and Shawmut St. Osgood & Osgood, Engrs., preparing plans.

**MANISTIQUE**—The Manistique Pulp & Paper Co. will build an addition to its plant. Estimated cost, \$500,000. H. J. Storer, consulting engineer.

### Missouri

**CIETWOOD**—Pfaeffle & Kelley have awarded the contract for remodeling their 200-ton plant to Carmody V. McGee, 631 Frisco Building, Joplin, and is in the market for lumber, mill hardware, engine, sludge tables, roofing and air compressors. Estimated cost, \$50,000. J. P. Kelley, superintendent.

**JOPLIN**—The C. H. & M. Mining Co. will remodel and improve its plant and build tramway and is in the market for new scales, sludge tables, lumber, rails, waste ties, wire cables, scales and engine. Estimated cost, \$6000. Burt Pitts, superintendent.

**ST. LOUIS**—The Mallinckrodt Chemical Works, 2nd and Mallinckrodt St., has awarded the contract for the erection of a factory at 100 Salisbury St. for the manufacture of chemicals to the A. H. Haessler Building & Contracting Co., Wainwright Bldg. Estimated cost, \$6000.

**ST. LOUIS**—The Pan Electric Manufacturing Co., 735 South 4th St., will build laboratories in connection with its proposed two-story, 40 x 50 ft. concrete and brick office building at 4090 Binkham St. Estimated cost, \$10,000. G. P. West, Wainwright Building, architect.

**WEBB CITY**—The Brown-Head Mining Co., Miami, Okla. will rebuild the 500-ton mill it recently purchased. A. Rowe, general manager.

### New Jersey

**CLAREMONT**—The Standard Oil Co., 25 Broadway, New York City, N. Y., has awarded the contract for the construction of a tank house and a filter house here to James Stewart & Co., Church St., New York City, N. Y.

**ELIZABETHPORT**—The Borne-Schrymer Co. has awarded the contract for the construction of a two story, 30 x 50 ft. concrete chemical laboratory, also a four story, 42 x 62 ft. addition to the city house to H. D. Best Co., Flatiron Building, New York City, N. Y.

**JERSEY CITY**—The Baker Castor Oil Co., Washington St., will build a reinforced-concrete addition to its plant. Estimated cost, \$75,000.

**NEWARK**—The Oxweld Acetylene Co., 640 Frelinghuysen Ave., will build a three story, 42 x 100 ft. addition to its plant. Estimated cost, \$50,000.

**TRENTON**—The School of Industrial Arts, West State and Willow St., will build an automobile engine laboratory in connection with the proposed two story, 56 x 65 ft. school on Quarry St. Frank Frederick, director.

### New York

**ALBANY**—The Patent Vulcanite Roofing Co., Tivoli St., has awarded the contract for the erection of a one story, 72 x 245 ft. concrete and brick factory to the Hamill Construction Co., Gay Bldg., Troy. Estimated cost, \$30,000. Noted Oct. 15.

**BINGHAMTON**—The Binghamton State Hospital will build an addition to its analytical laboratory. L. F. Picher, Capitol, Albany, architect.

**BROOKLYN**—The New York Quinine & Chemical Co., 99 11th St., will build a 50 x 100 ft. concrete and brick addition to its factory on Berry St. Estimated cost, \$25,000. T. Englehardt, 905 Broadway, architect.

**LONG ISLAND (Laurel Hill)**—The General Chemical Co., 25 Grand St., New York City, has awarded the contract for the erection of a two story, 40 x 116 ft. concrete and brick factory at Hall St. and Washington Ave., Laurel Hill, to Ledy & Moore, 105 West 40th St., New York City. Estimated cost, \$35,000.

**TONAWANDA**—The Acheson Graphite Co., Buffalo Ave., Niagara Falls, has awarded the contract for the construction of a new plant to the J. W. Cowper Co., Fidelity Building, Buffalo. Estimated cost, \$15,000.

### North Carolina

**ROSMAN**—The Texaway Tanning Co. will reconstruct its mill recently destroyed by fire; new machinery will be installed in same.

**WILMINGTON**—The city will improve its water-works to include a reinforced concrete sedimentation basin having a capacity of 1,500,000 gallons, a 5,000,000 gallon centrifugal steam driven pump and four 15 ft. additional filter units, etc. J. Newton Johnson, city engineer, preparing plans.

### Ohio

**AKRON**—The Quick Rubber Co., Home Ave., will build a factory. Estimated cost, \$25,000. G. W. Reid, general manager.

**CLEVELAND**—The Cleveland Brass & Copper Mills Co., 322 Guardian Building, has awarded the contract for the construction of a one story, 77 x 130 ft. concrete, brick and steel factory on Rabbit Rd., to Craig Curless Co., Guardian Building. Estimated cost, \$50,000.

**LORAIN**—The Cleveland Salt Co., 5312 Central Ave., Cleveland, will build a chemical plant here, consisting of six buildings, one and two stories high. H. G. Finley, 503 Union Building, Cleveland, engineer.

**NORWOOD**—The city plans an election on November 5 to vote on a \$50,000 bond issue for the construction of a water softening system. Allen Klessinger, city engineer.

**PARMA** (Cleveland P. O.)—The Swift & Co., 3240 W. 15th St., will build a two story, 50 x 75 ft. concrete, brick and steel fertilizer factory. Estimated cost, \$25,000.

### Oklahoma

**CENTURY**—The Federal Lead and Zinc Mining Co. will build new incline hoister skids and remodel its 400-ton concentration plant. It is in the market for lumber, cross ties, concrete, chain, making machinery, ore cars, hoister, wiring, cables, belts, engine, pipe, roofing and track. Estimated cost, \$35,000. W. M. Martin, superintendent.

**GROVE**—W. T. Croslin and George F. Clark will build a kaolin plant and is in the market for engine, boiler, lumber, concrete, hardware, chain, making machinery, kiln, dryers, track, cars, belts, pumps and roofing. Estimated cost, \$25,000.

**STILLWATER**—The city will build a filter plant, boiler room, engine room, etc.; filtering equipment having a capacity of 850,000 gallons per hour will be installed in same. J. L. Moore, city clerk.

### Oregon

**BEAGLE**—The Rainier Quicksilver Co. will enlarge its plant and is in the market for furnace equipment for same. Estimated cost, \$5000. Samuel Bertleson, superintendent.

### Pennsylvania

**CLOYLAND**—The Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of a toxic gas plant to the Cleveland Construction Co., 1023 Citizens Building, Cleveland, Ohio. Estimated cost, \$2,000,000.

**EMPORIUM**—The Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of eight units for the manufacture of explosives, located near the plant of the Aetna Explosive Co., to the Leonard Construction Co., 332 South Michigan Ave., Chicago, Ill. Estimated cost, \$2,000,000.

**HEIDELBURG**—The Aetna Chemical Co. will rebuild its fusion building recently destroyed by fire.

**MOUNT UNION**—The Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of a plant here for the manufacture of explosives to the Leonard Construction Co., 332 South Michigan Ave., Chicago, Ill. Estimated cost, \$1,000,000.

**PHILADELPHIA**—Powers, Weightman & Rosenkrantz, 916 Broad St., has awarded the contract for the construction of a factory for the manufacture of chemicals to R. C. Ballinger, 17th and Arch Sts. Estimated cost, \$6000. Noted June 15.

**PHILADELPHIA**—The Tigra Steel and Iron Co., 52nd St. and Gray's Ave., will build a 24 x 60 ft. water softening plant for its gun plant here.

### Rhode Island

**EAST PROVIDENCE**—The Rumford Chemical Works, 231 South Main St., has awarded the contract for the construction of a 1-story, 50 x 92 ft. addition to its plant to William Merchant, Inc., 186 Weybosset St. Estimated cost, \$18,000.

### South Dakota

**PLATTE**—C. F. Slate, city auditor, will receive bids until November 4 for the construction of a sewerage system and sewage disposal plant involving approximately \$190 lin. ft. 15 in. and 1200 lin. ft. 12 in.; 1465 lin. ft. 10 in. and 26,075 lin. ft. 8 in. sewer, together with necessary appurtenances, septic tank, sludge bed and sand filter bed.

### Tennessee

**MEMPHIS**—The Memphis Gas & Electric Co. has awarded the contract for the construction of two concrete buildings and a suburban house and the installation of 27 ovens to Phillips Lang Co., 343 Dearborn St.

### Texas

**AUSTIN**—The city will receive bids until Oct. 31 for the construction of sewage disposal plant. A. P. Woolridge, mayor.

**HONEY GROVE**—The city will build a hypochlorite disinfecting plant. Address the Mayor.

### Virginia

**NORFOLK**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will build a galvanizing plant, oxyacetylene and gas welding plant here. Specification No. 3333. Estimated cost, \$10,000.

**OAK**—The Virginia Mari Co., Box 1594, Richmond, is in the market for complete equipment for a lime and fertilizer plant.

**PORTSMOUTH**—The City Gas Co. and the United States Housing Corporation will build a gas plant to furnish sufficient gas to the Government settlement at Paradise Creek and Villa Heights; plans include the installation of machinery, laying of pipe, etc. Total estimated cost, \$175,000 to \$200,000.

**RICHMOND**—The Air Reduction Co., 120 Broadway, New York City, N. Y., has awarded the contract for the construction of a 60 x 102 ft. concrete chemical plant for the manufacture of oxygen, nitrogen and acetylene gases, to the James Mitchell, Inc., 76 Montgomery St., Jersey City, N. J. Estimated cost, \$30,000.

### Washington

**TACOMA**—The Skinner & Eddy Corporation, 1599 Railroad Ave., S. will build a large electric smelter here. Estimated cost, \$750,000.

**VANCOUVER**—The Rand Iron Works, 608 Ingalls St., will build a furnace room. Estimated cost, \$6000.

### West Virginia

**BELLE**—The Charleston Chemical Plant will rebuild its factory destroyed by fire, entailing a loss of \$400,000.

### British Columbia

**GRAVES POINT**—The Granby Consolidated Mining, Smelting & Power Co., 713 Granville St., Vancouver, will build a by-products plant here. Estimated cost, \$1,250,000.

**POWELL RIVER**—The Powell River Pulp & Paper Co. will rebuild its mill recently destroyed by fire.

### Ontario

**HASTINGS**—The Hastings Tanning Co. will build a one and two story, 200 x 200 and 40 x 90 ft. tannery. Estimated cost, \$50,000.

**B. E. Parks & Sons, Grand Rapids Savings Bank, Grand Rapids, Mich., architect.**

**KIRKLAND LAKE**—The Wright-Hargrave Gold Mines will build a mill and cyanide plant to have a capacity of 45,000 tons per year. Estimated cost, \$150,000. A. Wendy, superintendent.

**LONDON**—The City Council will build a low level interceptor and sewage pumping plant, also sewage disposal works. Estimated cost, \$300,000. H. A. Brazier, engineer.

**TORONTO**—The Galena Signal Oil Co., 134 Royce Ave., has awarded the contract for the construction of a concrete oil plant to the Toms Contracting Co., Kent Building. Estimated cost, \$60,000.

## Industrial Notes

**THE NATIONAL ANILINE & CHEMICAL COMPANY, INC., 21 Burling Slip, New York,** announce the appointment of Mr. W. W. Jones as the manager of the essential oil and gum department. He was formerly manager of the New York office of Frederick Stearns & Company.

**THE CHEMICAL EXPOSITION COMPANY** wish to announce that they will be located hereafter at 405 Lexington Ave., New York City, instead of the Grand Central Palace, which has been taken over by the Government.

**THE UNITED ALLOY STEEL CORPORATION, Canton, Ohio,** will open a sales office at the Swetland Building, Cleveland, which will be in charge of I. J. Shults.

**THE ZIRCONIUM SYNDICATE, LTD. of Great Britain,** are now manufacturing white zirconium, practically pure. It is believed that the production of zirconia on a substantial scale and at a commercial figure has never been accomplished before outside of Germany.

**THE NEW JERSEY ZINC COMPANY** have issued a new set of books entitled "Elements," "Metals," "Roller Zinc" and "Zinc Dust" which they call a "Handy Reference Library of Zinc Products." Each booklet briefly describes certain zinc products giving information that the average person might like to know.

**THE INDUSTRIAL ELECTRIC FURNACE CO., Chicago,** makers of the Snyder Electric Furnace, are installing a five ton furnace in the plant of the Zimmerman Steel Company, Bettendorf, Iowa. It is a three-phase furnace, designed for acid operation, and will be used for general work. C. H. Atherton, manager of the Zimmerman Steel Company, ordered the installation to replace the converter which they had been using.

**THE ELECTRO BLEACHING GAS COMPANY** has suffered so many losses in its technical forces due to the demands for war purposes that it has been necessary to discontinue the Chicago office. Mr. G. R. Ellis, who has been in charge of the Chicago territory has been transferred to the Niagara Falls plant and placed in charge of the office work.

**THE PERCOL CHEMICAL CORPORATION** has just bought a large manufacturing plant in Buffalo, N. Y., and will commence operations Nov. 1, 1918. Their specialty will be electrochemical products.

**THE AMERICAN NITROGEN PRODUCTS COMPANY** announce the opening of Eastern offices in the Woolworth Building, New York City, where the usual business courtesies will be gladly extended.

**MR. R. D. KEHOE** announces that he has disposed of his interest in the Machinery Utilities Company, Inc., and severed all connections therewith. He also announces the formation of the Technical Products Company, Inc., with offices in New York, Chicago and St. Louis, for the purpose of covering special fields of work not hitherto taken up by the Machinery Utilities Company and on a broader scale. The new organization will maintain a staff of technical men for the purpose of purchasing inactive equipment and placing it in essential industries. The new organization will not compete with the Machinery Utilities Company, Inc., but will enter other fields of work.

**THE WHITLOCK COIL PIPE COMPANY, Hartford, Conn.,** announces the opening of Eastern office at 40 Congress Street, under the management of Mr. W. B. Horr, who was the former Rochester representative.

**THE PALO COMPANY, 90 Maiden Lane, New York City,** have taken over the plant of Otto P. Weisswange of Mt. Vernon, N. Y., manufacturing precision instruments, thermometers and pressure meters, to meet the requirements of the Bureau of Standards. This plant was bought mainly to fill Government orders.

**THE CELLULOSE CO., New York City,** which is financed by Vickers Co. and Nobel Co., London, will commence building the \$2,000,000 cellulose and rayon manufacturing plant recently announced by the War Department. For the duration of the war the cellulose products will be taken over by the Government for armaments; after that the company intends manufacturing acids, drugs, dyes, etc., from cellulose and other materials.

**THE BON AIR COAL AND IRON CORPORATION, of Nashville,** is building a wood chemical plant at Lyles, Tenn., in accordance with contract to supply the Government with materials for explosives manufacturing. The plant will be in operation about Dec. 1. This factory expects to produce 100,000 to 200,000 gallons of wood alcohol, 40,000 pounds of acetone, 10,000 and 10,000 bushels of charcoal per day. The Government will take all the alcohol and acetate of lime for the purpose of manufacturing explosives; the output of charcoal will be burned in the Bon Air Coal and Iron Company's iron furnace.

**RICKETTS & COMPANY, INC.,** mining, metallurgical and chemical engineers, have opened new laboratories at Room 509, 80 Maiden Lane, New York City. They are now equipped for assay and analytical work of all kinds, especially analyses of glycerin and manganese.

**MESSRS. A. E. S. THOMPSON & COMPANY,** handling large quantities of chemicals and dyes in the Oriental market, has established a branch in the Merchants Exchange Building, San Francisco.

**THE INTERNATIONAL OXYGEN COMPANY** recently sent Mr. George Quelch, one of the staff engineers, to England to supervise the installation of a 400-cell plant of I. C. C. Unit oxyhydrogen generators for the British Admiralty. Mr. Phillips Wesley, technical manager in charge of the oxyhydrogen plant and sales office of the company at Pittsburgh, and Mr. Jack Heller has joined its New York sales force, succeeding Mr. Barnitz.

## Manufacturers' Catalogs

**THE CHEMICAL CONSTRUCTION COMPANY, Charlotte, N. C.,** has published an attractive pamphlet descriptive of its service in the design and construction of chemical plants. Considerable space is devoted to a description of a chemical concentrator for the concentration of sulphur and phosphoric acids.

**THE INTERNATIONAL OXYGEN COMPANY, 115 Broadway, New York City,** calls attention to its new 400-cell oxyhydrogen generator of the company, gives dimensions and capacities, and presents working plans of two typical plant layouts of common capacity showing the extreme compactness of this new cell.

### Victory Over Might

IN SECURING an absolute defeat of the Teutonic Powers, we believe that the Allies have extracted the Might from the German banner "Might Is Right." The obligations to the world that the German people have incurred will not be cancelled by their surrender of 5,000 cannon, 2,000 airplanes, 160 submarines and other useless war material in proportion, nor by the payment of gold indemnities. The loss that they shall feel most will be foreign good will, and try as hard as they may, they shall never be able to put warmth into the heart that has chilled.

The predominant characteristic of convicted culprits as reported by the prison welfare worker is the desire of the criminal to make it appear that he is not bad. He shrinks from making a confession of his guilt, though he finds great solace in bearing witness against some one else. Try as they may, the German people will have a difficult time to convince the world that they did not support the aims of their infamous government with heart and soul. The allied army did not merely upset the Hohenzollern autocratic militarism but it subjugated a nation which since the days of Rome has been banding into plundering hordes under the banner of "Might Is Right."

Even in the realm of the chemical industry, the wolf was the foster mother. The work of Ostwald, Haber, Nernst, Fischer, advanced into the chemical realm under the same command, "Vorwärts!" that sent the pillagers into Belgium. It was the "Halt!" by the same voice that caused dyes to be sold in all countries outside of Germany at prices designed to keep for their nitrating equipment all the Might.

### Making Blast Furnaces and Steel Works Fit

THE opinion is practically unanimous that for several years of peace, following a war of more than four years' duration, which has made its effects keenly felt in the uttermost parts of the earth, there will be trade expansion and much new construction, with a heavy demand for practically all commodities at remunerative prices. Much has been said of "reconstruction," but if the term be construed narrowly to mean restoration in the war area, the history of the period will probably show reconstruction of business throughout the world as of much more importance commercially. There will be trade expansion everywhere, new ideas leading to new ventures and much construction everywhere. The early idea that capital would be scarce after the war on account of so much destruction of property has yielded to the new conception of what can be done financially by

the immense war loans that have been so readily floated. Just for one illustration, municipalities are likely to employ the Liberty Loan methods with which their men, women and children have become so familiar, for the purpose of floating popular loans for municipal improvements, replacing the hitherto universal practice of the city fathers dealing direct with the bankers.

Before the world really starts at full speed on this work, however, there must necessarily be a period of sweeping readjustments. That is fully recognized, and the only debate to-day is as to the number of months that will be required. In the case of steel, the line of demarcation between the readjustment period and the period of world activity commercially will be drawn with particular sharpness, by reason of the fact that whenever there is a heavy demand for steel the major part of it is going into construction, into works planned by the investor, who must buy at prices bearing the proper relation to the expected returns over a period of years, ranging perhaps from ten to twenty-five, according to the nature of the venture.

Of this period of readjustment the iron and steel industry should not lose one day. It has a very important job immediately ahead of it, in making all its plant facilities, its blast furnaces, steel works and rolling mills altogether fit for the work ahead of them. Many are quite unfit now. For fully three years the productive capacity of the American iron and steel industry has been taxed. For about two years it was merely taxed in an ordinary commercial way. The industry was engaged in selling, producing and making money. For nearly a year past its governing motive has been a higher one. The War Industries Board has insisted continuously on maximum production as a patriotic duty, never mind how expensive the operations or how uneconomical some practices might be, if only they assured additional tonnage of steel to meet the great emergency. First there was the damage to plant facilities that always occurs when operations are profitable, the cost being counted and considered warranted, and then there was the extra damage, when the cost in dollars was not counted.

In the first place, all this damage must be repaired and all facilities put in the best condition. In the second place, there has been a sweeping rearrangement in the relative importance of different items of cost, whereby the cost of plant facilities does not bear the same relation to operating cost as formerly obtained. With high wage rates, labor saving machinery is indicated in many places where it was not formerly indicated. Again, under the stress of demand for the last possible ton of steel, capital expenditures have been made with a view of increasing tonnage output rather than reducing cost per ton. The former continuous progress toward more and more economical methods of production has been very largely interrupted. With its greatly increased tonnage capacity the industry must now be much more concerned with capital expenditures that will reduce cost of production than with those that contemplate merely an increase in tonnage. Again, while the iron and steel industry has never had all the capital its engineers and metallurgists desired to invest, it is better provided with capital than ever before as a result of several years of unusual profits. Thus the industry finds itself in an entirely new set of conditions.

The big job thus indicated as lying before the iron and steel industry is one that must be done quickly if it is to be done to the best advantage. The chief time for it is the interim period, of uncertain duration, between the heavy demand for product that has hitherto existed and the heavy demand that is to come when trade has found its stable basis for a period of years of general activity. While the investor in construction work that requires steel may wait until costs find their level, the producer of steel cannot keep him company, for he cannot revamp his works and produce maximum tonnage at the same time.

### Commercial Bribery— Trade Commission Acts

THE FEDERAL Trade Commission on October 24 ordered the firm of John F. Buckie & Son, makers of printers' rollers, Chicago, to discontinue the practice of giving gratuities or presents to employees of their customers or to those of competitors' customers, with a view to influencing the purchase of supplies. Another concern was cited to appear before the Commission on December 6 to answer an allegation to the effect that it had been practicing commercial bribery in the sale of its dyestuffs.

This sort of thing must stop. The greatest of our coal-tar dye concerns has taken the firm stand that no bribery shall be practiced and we understand that the leading houses in the industry are following suit. Before the war the bribery of dyers in the color industry was nothing less than outrageous. We have already quoted a remark of a veteran of the dye business which we shall repeat. "Everybody did it," said he, "and the only difference between the Americans and the Germans was that the Americans knew it was wrong and the Germans didn't." He is a man of charitable mind, but perhaps he was right. The point that we want to make is that the practice is too corrupting to allow anybody to engage in it. The penalty has been made severe, but that will not stop it unless there is an enlightened and honest public opinion to back up the law.

We recall one cheerful old hypocrite who sent handsome sums to the persons he would bribe with the memorandum that the remittances were for pew rent, and he soothed his gravely conscience with the observation that there was nothing wrong in inducing people to go to church. He was not in the chemical trade, we are glad to say. The legend is also told of a late philanthropist who lived his bespangled days in red hot affluence that early in his career it was his occasional habit to send his card in to the railway officials to whom he desired to make sales, accompanied by a sealed envelope. The latter contained the half of a thousand dollar bill that has been torn in two, and with it he gave the message that he had with him the answer to the letter. The answer, of course, was the other half of the bill. This seems hazardous, but he knew his trade.

There is a great element of sport in crime, which is its chief appeal to some minds. And there is humor in it, as there is in most adventure. But it is expensive, viciously expensive to the general welfare. Bribery in trade is also like cheating at cards in that it indicates a fault in him who practices it that renders him unfit to associate with those who do not cheat. Bribery

is a disease, whether it comes through the front door or the back, and it soon spreads itself, no matter how great the effort to hide it.

There are some puling, whining polyps that do not ask for bribes out and out, but always and forever intimate that if they only had certain advantages they could do a great deal for the man with goods for sale. They beat all around the bush with the mumble that they don't want anything but what is right—and then they begin all over again and go on to tell how trustworthy they are keeping secrets. They might also be called the mosquitoes of business. If somebody were to spit upon them they would drown.

### Employment Managers and the Wage Earners

WE PRINT elsewhere an article by Mr. C. T. CLAYTON, Director, Training and Dilution Service, United States Department of Labor, on "Who and What Is the Employment Manager?" It is propaganda sent out by the War Industries Board with a view to avoiding after-the-war disorder. When we bear in mind that some twelve million men and women are now engaged in the production and distribution of war supplies, it stands to reason that the transfer, in the main, of so vast an industrial army to the arts of peace calls for intelligence, caution and character. Even more serious will be the placing of returned soldiers.

We are persuaded that the art of employment must receive more intelligent attention hereafter in industry than it has received heretofore. To aid in this the Employment Management Section of the War Industries Board has provided courses of instruction at certain institutions of learning to which employers may send accredited representatives for the purpose of informing themselves on such theory and recorded practice as is available on the subject. The courses run from six weeks to two months and are conducted under the auspices of the Departments of Labor, War and Navy, the United States Shipping Board and the Chamber of Commerce of the United States. Tuition is free.

As industry has grown bulky as well as great, employers of thousands have not thought to urge their men to read as well as to think, although this is done in the Army. Nevertheless industrial workers have read and thought, and they have reached some amazing conclusions, among which is the dictum that life, in nearly all of its aspects, is a problem in economics. The standardized socialist will quote statistics and figures to prove this until any one unfamiliar with his arguments becomes bewildered. And yet it is no strain upon the mind to grasp the idea that there is far more than economics in the business of living. One trouble is, though, that clear thinking is hardly possible when conditions are unfavorable, and unfavorable conditions often obtain in industrial life.

Where poverty pinches life is a problem of economics. We mustn't forget that. On the other hand, as soon as decent living conditions arise, economics in a personal sense becomes but a function of sanity, while taste and habit play more important parts. Psychologists say that if a statement is made to a child constantly and repeated without contradiction, by the time he grows up he is likely to regard the statement as a fact, no matter how absurd it may be. Now a surprisingly large number

of factory hands have grown up under the constant iteration and reiteration that life is wholly a problem in economics, and we have to meet this illusion almost as an *idée fixe* time and again. Carried to its ultimate conclusion and without the development of taste and the cultivation of habit it leads to anarchy, riot and Bolshevik terror. But the idea is exceedingly popular and, we repeat, when poverty pinches it is right; then economics becomes a question of life or death.

Deputy sheriffs do not cure the illusion. Neither will overpayment of wages, and letting it go at that. We have long emphasized the fact that the feeble minded drift naturally into industry and that labor organizations that carry them as equals do so to their great detriment. According to a Government publication, from five to fifteen per cent of all applicants for jobs in industry are feeble minded. Give them more than a hundred dollars and you are buying trouble.

Industrial obligations are not fulfilled by the payment of wages. They are not even completed by good housing conditions. Something more is required, and that is the development of an enthusiastic, loyal, intelligent working staff. If an industrial organization degrades the quality of citizenship of its workers and by its own fault or neglect permits a situation to arise whereby their progeny become crippled in mind or wayward, the country is better off without that establishment. We cannot afford to make bad Americans, either directly or indirectly, whether the parents be born here or in Italy or Russia or anywhere else. Our boys are fighting nobly for us; we mustn't spoil their land or their people, now or at any other time.

We have no specific cure to recommend. Sometimes a bonus system works and sometimes it doesn't. Sometimes an employment manager is a great help and sometimes he is an ass. The point we want to make is that the workers in an industrial establishment are citizens, real or prospective. We live in a democracy. It is the measure of their intelligence which in the end will guide our country. The responsibility for their development in mind and understanding and in the art of living is a big and solemn thing. We know an otherwise excellent man engaged in industry who misses this point. The more he prospers the worse it is for his home town.

### Pure and Applied Chemistry in England

WE PRINT elsewhere the presidential address of Professor WILLIAM JACKSON POPE before the Chemical Society of England, and we commend it to our readers for its sound doctrine, clear vision and its happy grace of expression. The situation of pure and applied chemistry in England in 1914 was not exactly the same as it was in America but in a way we were all in the same boat. We listened devoutly to the siren voices of German privy councillors, professors, consular agents and commercial travelers who sang in chorus the refrain that chemistry cannot thrive outside of Germany. We lacked the training, the scholarship, the precision of thought and habit and every requisite quality to practice chemistry in its refinements, they declared—and we listened attentively without calling their bluff.

We congratulate the Chemical Society on the happy selection of its president and we wish it all success under his guidance.

### Measuring Odors

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—In commenting on the paper of V. C. Allison and S. H. Katz, you say, on page 549 of the October 1 issue of *CHEMICAL & METALLURGICAL ENGINEERING*: "So far as we are aware, this is the first instrument designed to establish olfactory standards, and we sincerely hope that studies on the subject may be continued." Unfortunately for the glory of our American chemists, Allison and Katz have been anticipated by a Hollander, Professor H. Zwaardemaker of the Physiological Laboratory at Utrecht, who not only has designed an instrument for a similar purpose but has obtained a whole series of results of far-reaching significance by its use. A popular, although quite comprehensive, exposition of this field is given by Professor Zwaardemaker<sup>1</sup> himself, while another clear statement of these researches will be found in a general article by J. Languier des Bancel's.<sup>2</sup>

In passing, attention may be drawn to the fact that the word "odormeter" adopted by Allison and Katz hardly corresponds to the best English usage. Should it not be either "odorimeter" or odorometer"? I have seen the assertion<sup>3</sup> that Zwaardemaker speaks of "olfactometry" when measuring the sensitiveness of the sense of smell, and of "odorimetry" in determining the intensity of odors, although my impression is that he has given up the latter term, using the olfactometer for both purposes. Before leaving the subject of Zwaardemaker's work, I wish to draw attention to the Utrecht dissertation of J. Hermanides (1909), which contains extremely important information on an interesting phase of the work resulting from the application of the olfactometer in Zwaardemaker's laboratory. I have not been able to find this pamphlet in the larger Chicago and New York libraries, and would appreciate any hint helping me to locate a copy.

The latter part of your comment, wherein you express the sincere hope that the work may be continued, must receive a most hearty second from all American chemists, for there is surprisingly little being done in this promising field of the relation between chemical constitution and odor.<sup>4</sup> To illustrate that interest in this subject is not altogether dormant, attention may be drawn to the following free translations from the only book that claims to treat the matter.<sup>5</sup> In the preface, Cohn writes:

"A knowledge of the nature of perfumes, their physical, chemical and physiological properties, is a necessary preliminary for their synthesis. Too much attention cannot be paid to this subject, if for no other

reason than the desire that German science may assert its preëminence in this field also of chemical activity." Again, on page 64: "The investigation of perfumes, the determination of their constitution and their synthesis, has made the most progress in Germany, because here strictly scientific principles and not empiricism has been the guide. Not without reason do the French see in this successful co-operation of science and industry in Germany a serious threat to the existence of their own industry."

Personally I believe the subject of smell and odors will eventually be of great significance to chemical science and industry and that it will attain an importance transcending even the goal sought by far-sighted chemists in the line of synthetic perfumes; it is therefore a matter of satisfaction to see American chemists doing good work in this neglected field. In closing allow me to compliment the member of your staff who is so alert as to recognize important work and who acts on his judgment in urging its continuance.

### Copper in Converter Slags

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Your editorial of April 15 and Mr. Forest Rutherford's letter in your issue of July 15 lead me to give some of my own observations on the behavior and composition of converter slags.

Mr. Rutherford's experiments confirm my belief that it is impossible thoroughly to clean converter slag by pouring it into blast-furnace settlers. This practice would scarcely have gained any popularity did not the great dilution with furnace slag mask the true losses.

Some years ago I determined the copper as sulphide and oxide or silicate in an average sample of converter slag made during a considerable period at a large smelter. These were 0.48 per cent and 1.44 per cent, respectively, showing that 75 per cent of the total copper existed in the oxidized condition, although there was 1.70 per cent sulphur in the slag, more than enough to combine with all the copper present. This shows clearly why settling alone does not produce clean slags. If this slag were poured into a blast-furnace settler a little of the oxide might be reduced by contact with the matte, but surely not a large proportion of it.

Mr. Rutherford evidently believes "that converter slags cannot be cleaned without resmelting them, and in doing so, changing the chemical composition." If by "composition" he refers to the combination in which copper exists in the slag he is evidently right, but if to the relative proportions of silica, iron oxide and other bases, I believe he is only partly so. In support of this I shall quote the results of experiments by Mr. John W. James (*Eng. and Min. Journal*, vol. 97, p. 1114).

Mr. James passed into a reverberatory furnace converter slag which by settling had been reduced in copper content to 1.25-1.50 per cent. By a treatment with green poles and charcoal 40 per cent of the

<sup>1</sup>Ladenburg, "Handwoerterbuch der Naturwissenschaften," Band IV, pp. 967-975 (G. Fischer, Jena, 1913).

<sup>2</sup>L'Odorat: Revue generale et critique," Archives de Psychologie, X, 1-46 (1910).

<sup>3</sup>Schimmel's Semi-Annual Reports, English edition, October-November, 1904, pp. 194-199.

<sup>4</sup>Gertrud Woker, "The Relations Between Structure and Smell in Organic Compounds," Journ. Phys. Chem., X 455-473 (1906), is probably the only contribution in an American scientific journal in this field.

<sup>5</sup>Georg Cohn, "Die Riechstoffe," in Bolley's "Technologie," VI 2 (Braunschweig, F. Vieweg und Sohn, 1904).

copper was reduced. He then threw in a little pyrite and brought the copper down in a few minutes to about 0.4 per cent, a normal loss in reverberatory smelting. He concluded that the copper was present in the oxidized condition, and thought there was insufficient sulphur in the slag to combine with all the copper. He suggested that where iron flux was not required the treatment with pyrite would be a satisfactory solution of the problem.

Where converter slag is treated in reverberatory furnaces it is usually charged with roasted or raw concentrates, or both. A fair reduction is sometimes obtained in this way, but I would suggest the addition of pyrite in large lumps as being preferable. These would sink to the bottom and lose half their sulphur by heat alone, the vapor of sulphur rising through the supernatant slag and having an excellent opportunity of reducing the oxide of copper. If siliceous and calcareous ores were available these could of course be added to advantage, but I believe the reduction with pyrite is the essential thing, and no great change in chemical composition would be necessary to produce a satisfactorily clean slag.

Even when smelted in a blast furnace, converter slags are responsible for increasing the copper content of the furnace slag to some extent, both by increasing its specific gravity and consequently hindering the separation of matte and slag, and by introducing oxidized copper. Direct determination of oxidized copper in furnace slags has shown that this loss increases as the converter slag on the charge is increased. This is similar to, though less than, the increase in slag loss when copper silicate ores are smelted in a blast furnace.

Your editorial raises the broader question: How is copper held in a furnace slag? It is not my wish to go fully into this question, as I have already discussed it in detail. (*Eng. and Min. Journal*, vol. 100, p. 215, 263, 305). But I may state that analyses which I made of blast furnace slags from three large plants showed that from 50 per cent to 75 per cent of their copper was in the oxidized condition. The proportion would probably be lower with a heavy sulphide charge.

FRANK E. LATHE.

Chuquicamatn, Chile.

## Role of Colloids in Chemical Processes

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—I read with much interest your article on the "Role of Colloids in Chemical Processes" and note that in numerous fields colloidal action has been recognized.

Under the heading of "Metallurgy" however, nothing has been said of the relationship of colloid chemistry to the flotation process. Some interesting facts are related under "Soap Manufacturing" and it is queer that the very fact that the flotation process is based solely upon colloidal chemistry actions is not more recognized. Only a few days ago I read an article by Jackson Pierce in the *Mining & Scientific Press* on the action of colloids in the flotation process, based upon the assumption that slimy mineral and gangue represent a colloid; in other words, written with a total ignorance of the actual meaning of colloid chemistry, yet it is beyond all question of doubt that just the same as in the soap industry and in the dye industry definite colloidal actions are recognized and utilized so the flotation process is absolutely fundamentally based upon the formation of colloids from the oils, tars, coal-tar intermediate products

and the like used, and it seems too bad that probably the biggest percentage of flotation men are still laboring under the impression that mud in the flotation cell represents the colloids and that the true colloid action in the flotation process is therefore overshadowed and drowned by these mediæval ideas. For over a year I have been writing articles from time to time trying to impress upon the flotation industry the importance of research work in the direction of colloidal chemistry, but so far with little success.

I have installed numerous and expensive devices in my laboratory to test out such colloidal actions and am fully satisfied that colloid chemistry absolutely explains the mystery of the so-called flotation phenomena. I have corresponded with Dr. Fisher, who translated Ostwald's "Lectures on Colloid Chemistry," and he joins me in this opinion.

As you say in your note that such publication is timely, I suggest that you open a discussion on that subject and I shall be glad to enter it with what results I have obtained in my own research work.

A. SCHWARZ.

## Reinforced Concrete vs. Salt, Brine and Sea Water

To the Editor *Chemical & Metallurgical Engineering*

SIR:—In your issue of Oct. 15, 1918, there appears an article by H. J. M. Creighton on the subject "Reinforced Concrete vs. Salt, Brine and Sea Water."

It seems to me Mr. Creighton has drawn conclusions which are scarcely warranted by the facts presented. Without a knowledge of the actual location of the various structures referred to in this paper it is difficult to get at the facts, but it is quite apparent from a careful study of the photographs submitted that at least in many of the cases the structure was either improperly designed or improperly constructed.

The regulations of the Joint Committee on Concrete and Reinforced Concrete and all properly prepared specifications for such work require that the reinforcement shall have a protection of concrete of not less than one inch. The Joint Committee devotes a paragraph in its report to the subject of corrosion of metal reinforcement which reads as follows:

"Tests and experience indicate that steel sufficiently imbedded in good concrete is well protected against corrosion, no matter whether located above or below water level. It is recommended that such protection be not less than one inch in thickness. If the concrete is porous so as to be readily permeable by water, as when the concrete is laid with a very dry consistency, the metal may corrode on account of the presence of moisture and air."

A careful study of photographs 3, 7, 8, 9, 10, 12 and 15 would indicate that the metal did not have one inch of protection, and undoubtedly rusting of the reinforcement and, therefore, cracking of the concrete would have occurred in the presence of moisture, regardless of whether the moisture contained salt, brine or sea water. It would also appear from some of the other photographs that the concrete in several cases was not of the best quality, possibly being porous and thus subjecting the reinforcement to early and undue corrosion.

W. M. KINNEY.

## Western Chemical and Metallurgical Field

### Manganese In California

SUCCESSFUL prospecting and development of manganese-producing mines have gone on at a remarkable rate since Americans were convinced that they must supply the deficiency of ore formerly supplied by ship from Brazil and elsewhere. Not only is a very considerable quantity of high-grade ore now being produced for direct smelting into high-grade ferromanganese, but much ore is being concentrated to eliminate undesirable silica and other impurities, notably at Philipsburg, Mont., as described in our issue of June 15, 1918.

#### ORE DRESSING TESTS

E. A. Hersam has conducted some experiments on ores of the latter class, and the results are given in the University of California Publications in Engineering. The results encourage the author to say that if each ore is studied carefully before large expenditures are made for a treatment plant, there will be found abundant reasons for developing the deposits of low-grade ores at this favorable juncture. It is elsewhere officially reported that more than 200,000 tons of siliceous manganese ores are now developed in the Coast regions alone.

Little of the California ore promises a successful mechanical separation except after fine crushing. The manganese minerals are of low density, often approximating that of the gangue, and slime excessively during crushing. Thus while a clean concentrate can be made on machines acting under the principles of hindered settling, most of the values appear in the slimes of an intermediate grade and are difficult if not impossible to treat. Flotation tests on this material were unpromising in every way. Magnetic tests were most favorable, indicating that about 75 per cent of the manganese may be recovered in marketable grade. On the other hand, electrostatic tests were erratic and unsatisfactory. Very encouraging results resulted from lixiviation tests. For instance, 40-mesh ore was leached with a solution containing 10 per cent sulphuric acid and 10 per cent ferrous sulphate, circulating through a diaphragmed electrolytic cell, operating at 2.5 volts and 100 amperes per square meter. Extraction of the manganese from the ore was satisfactory; the metal was deposited as a hydrated dioxide (80 per cent  $MnO_2$ ) on the anode, and the acid and reducer continuously regenerated. Certain features of this process have received careful examination, others are under minute investigation. Deposition may attain the rate of 1.62 grains of dioxide per ampere hour, and the cost of the process on a large scale is estimated at \$15 per ton of product, exclusive of electrical energy.

#### PRODUCTION OF SILICO-MANGANESE

In the meantime the Pacific Electro Metals Co.'s plant at Bay Point (briefly described in our issue of Aug. 1, 1918) is reducing siliceous ores to an alloy of iron, silicon and manganese. On account of the very small slag volume produced by their electric furnace, the recovery of manganese is excellent—approximating 90 per cent—and the current efficiency is superior to that

when producing ferromanganese. The alloy is not widely known among American steel makers, although it was imported in considerable quantities prior to the war and is favorably regarded by at least one of the largest steel companies. France, England and Sweden have all been producers of this alloy, and are producing in quantity at the present time, while it is thought that it supplies practically all the manganese used by the German steel works. Electric furnacemen are fond of saying that in an alloy, carbon and silicon are mutually exclusive, consequently properly made silicomanganese may contain less than 0.5 per cent carbon, which should make an attractive material for use in the production of low carbon steels and ingot-iron.

#### FERROMANGANESE ON THE COAST

At least three companies are equipped to produce ferromanganese on the Pacific Coast. The Western Reduction Co. of Portland, Ore., has a 700-kw. furnace, the Billroe Alloys Corporation of Tacoma, Wash., a 500-kw. furnace, while the pioneer Noble Electric Steel Co. has been devoting a great deal of attention to ferro-alloys for many months past and has now two 1500-kw. furnaces in operation at Heroult, Cal. The Noble company largely produces its own raw materials; its production of high-grade manganese ore amounts to about 600 tons per month from four mines in Shasta, Tehama and San Luis Obispo counties. Charcoal used for a reducing agent is produced by them in two localities in Mendocino County, one a pit-burning operation, seasonal in character, and the other in beehive kilns, which are continuously operated. Iron ore and fluxing limestone are both quarried from large high-grade deposits near the furnace-plant.

A considerable part of the 70 per cent alloy is consumed in the five open-hearth plants on the Pacific Coast. Since three-quarters of the steel produced in this region is sold directly to the Fleet Corporation, it is apparent that the local production of necessary deoxidizers is an essential war industry. The Noble Steel Co. also produces an 80 per cent grade of ferromanganese, which is shipped east to such plants as have permission to use it from the Ferro-Alloys Board of the Iron and Steel Institute. About 500 tons of alloy are produced monthly, and present indications are that this production can be maintained profitably even after cessation of hostilities.

#### National Potash Company's Plant Destroyed

During the latter part of September the potash plant of the National Potash Company, situated at Antioch, Nebraska, burned to the ground.

The National Potash Company is one of the "big six" in the Nebraska field as far as resources and plant are concerned. Construction on the plant was started only last November, and it had hardly been tuned up to capacity, due to delays in construction and low water in the lakes. Thus the greatest daily output was approximately 20 tons, and the total production had hardly affected the total for the region when the plant was destroyed. The remaining large producers are the Pioneer Potash Products Co., at Hoffland; the Nebraska Potash Works Co., the American Potash Co. and the Alliance Potash Co., all at Antioch; and the Hord Alkali Products Co., at Lakeside.

## War Emergency and Reconstruction Conference to Be Held at Atlantic City

**P**RELIMINARY plans for the War Emergency and Reconstruction Conference of War Service Committees to be held at Atlantic City Dec. 4, 5 and 6 are announced by the Chamber of Commerce of the United States through the general secretary, Mr. Elliot H. Goodwin.

Reconstruction will be given a prominent place on the program, as it is recognized this subject must be taken up by business men to the end that there may be placed at the command of the Government all available sources of information. The work of reconstruction suggests the creation of a federation of all war service committees that whatever study and planning is carried on may be on behalf of all business. War industries and non-war industries are concerned equally in the determination of reconstruction problems. All European countries already are under way with reconstruction plans.

The Atlantic City conference, a call for which was sent out last week by the War Service Executive Committee of the Chamber of Commerce of the United States, will include four general sessions and numerous group and committee meetings. Into the final session will be brought for final action all the proceedings of the meetings.

There will for four general sessions participated in by all the delegates. On Dec. 4 there will be both morning and afternoon sessions and on Dec. 5 and 6 morning sessions. The Chamber is engaged now in obtaining the best speakers available to discuss among others the following suggestions: reconstruction, industrial relations, raw materials and their control, price control, economic legislation affecting combinations, export and import operations, finance, etc.

The conference will be divided into groups at three sessions, the first to be held on the evening of Dec. 4, the second on the afternoon of Dec. 5 and the third on the evening of the same day. On the evening of Dec. 4 each war service committee will meet with its chairman to consider the problems of reconstruction as they affect that particular industry as well as to take up other problems which the war has demonstrated are vital to industry. On the afternoon of Dec. 5 the war service committees will meet in groups which are related as to their use of basic materials and as to their distribution problems, etc. With these groups will meet the commodity or section chiefs of the War Industries Board.

Related groups will form themselves into ten major groups on the evening of Dec. 5 to take up the question of raw materials, price control and subjects arising from related group meetings. After the general meetings of the committees of the related groups and of the major groups it is hoped there will be presented definite recommendations covering the reconstruction period, with the possibility of creating an executive committee empowered to gather data and to function with industries to meet the many problems that the nation's industries will be called upon to solve with the end of the war.

## War Industries Board May Be Reconstruction Agency

By WINGROVE BATHON

Washington Representative, McGraw-Hill Company, Inc.

**I**N CONNECTION with the possibility of a Reconstruction and Readjustment Agency being created by act of Congress, opinion is crystallizing in Washington along the lines that the members of the War Industries Board will most likely be appointed to this work in case the Overman bill, which is an administration measure and which provides for a commission of five members to be appointed by the President, is passed by the present Congress. There is every expectation that this bill will be passed, and the likelihood of its passage has been added to by the defeat for re-election to the Senate of Senator Weeks, who proposed a reconstruction measure which would have created a reconstruction agency composed of members of Congress.

In Washington it is now believed that if the Overman bill is passed President Wilson is likely to name as members of the Reconstruction Commission men like Bernard M. Baruch, chairman of the War Industries Board, and some of his principal associates. It is pointed out in Washington that while Senator Weeks has been defeated his idea of a legislative reconstruction agency has not necessarily died. In other words, it is expected that during the life of the present Congress Senator Weeks' idea will be pushed. But it is also pointed out in Washington that there is every likelihood that if a Congressional reconstruction agency were created, even admitting that the consent of President Wilson to do so could be obtained, the new Congress which takes office March 4 next would likely legislate out of existence, possibly by failing to appropriate money, the creature of the present Democratic Congress. All the present signs in Washington, however, tend to show that the Overman bill will be passed and that the machinery of the War Industries Board will be turned into after-the-war work behind the commission to be appointed under the Overman bill, under the probable leadership of Mr. Baruch as chairman of the new commission.

It is pointed out in Washington that the present agencies of the War Industries Board are in possession of complete data and information concerning the industrial, commercial, financial and transportation resources of the country. For this reason there are many who believe that the War Industries Board is the only agency equipped with machinery and supplied with the necessary information to give suitable guidance to business for after-the-war work.

There is no means of ascertaining or predicting what effect the elections of Nov. 5 will have upon business and the necessary reconstruction period to follow the war. It must be borne in mind that a great number of Republicans newly elected to the Senate and the House will not take office until March 4, 1919, when a new Congress will come into existence. There has been much newspaper comment to the effect that if the Republicans gained control of the House and the Senate there would in all likelihood be an extra session of the new Congress early next year at which members elected Nov. 5 would take their seats. It seems, however,

extremely unlikely that a Democratic President would call an extra session of a Republican Congress to deal with business matters such as will be involved in the reconstruction period, and it is almost certain that the present Democratic Congress, in view of the foreign situation, will hold on and remain at work in Washington until the very last minute before March 4.

Since the armistice was signed, members of the War Industries Board, more particularly committees of that board, are announcing in Washington their intention of preparing to return home and get ready for the reconstruction period which they must face in their own businesses. In some respects this attitude, while natural, is greatly to be regretted, according to the best opinion obtainable in Washington, because of the growing belief that the War Industries Board, which has done so much to guide business during the war, is so well fitted to continue to guide business during the reconstruction period.

## Address to Society of Chemical Industry\*

BY CHARLES E. SHOLES

PERHAPS you are as bored as I am to hear public speaking interspersed with stories. But when your committee overruled my protest and selected me to serve as Chairman of the Society of Chemical Industry, I immediately thought of the man up state who went into one of our New York hotels and ordered frogs' legs and got a check at \$2 a portion. He was furious and offered to furnish all the frogs' legs the hotel could use for a year at 10 cents a dozen, and a contract was duly signed. But no frogs' legs were ever delivered, and the man from up state finally admitted that he had been "deceived by the noise." I think that your committee was probably "deceived by the noise." However, we are all learning a good bit of discipline these days, and when your committee says "Carry on," there is nothing for me to do but obey.

But I want your help. Certainly organizations of this kind cannot be negative. They are either like a female auxiliary of masculine forces, or they will wield a real influence in making this wounded world whole again and in preparing our industries for the new conditions they must meet hereafter.

I do not believe that we are going to exterminate the German race or disposition. We are going to give them a severe beating, but after it is all over the same old dog will be wagging the same old tail outside the same old door to our markets, and we must see to it that he gets nothing which may be needed by our children. Our captains of industry can do much. You can do much. The Society of Chemical Industry should be an effective means of getting together.

And now may I presume to say a word concerning my recent experience and experiences? On the way to the train on that first day in the uniform of the Service a number of privates and junior officers saluted me, and a companion remarked it, until I explained (as I am very glad always to continue to realize) that it is the uniform, not the man, that is saluted. Also I hope it

is only for this reason that when one of our clean American boys clips his heels together and stands very erect and gives this uniform a snappy salute, I always have a sneaking wish to swap clothes and everything else I have for his youth and his opportunity of closer contact with this great race between good and evil.

And speaking of races, a professional runner once told me that the way to win a race was to "run as hard as you damn can—and then harder." Although this war is largely an industrial proposition and industries have been prolific in sacrifices, and I believe in them with all my American brain and blood, some of our best industrial racers got a bad start. They seem to have confused the real meaning of the tax on surplus profits, and I have repeatedly heard men contend for a high price, because "80 per cent of the profit is returned to the Government in taxes." But the facts are that the surplus profit tax is only designed to prevent some such bad behavior as we are trying to stop in Europe.

I am still looking for that officer who wears spurs to keep his feet on his desk. I haven't found him, but I have found the hardest-working lot of men I have ever seen striving earnestly with the biggest business proposition on earth, and accomplishing so much that is commendable that the exceptions and faults should be most readily forgiven.

And I'll tell you a secret—they are the best paid men on earth, because, though they only receive small sums of money, they are infinitely more proud of their jobs than any other group of men I have ever met.

May I take a moment more to ask your interest in some of the "C. P. heroes" of this war, who may be overlooked if you allow it? At a recent Sunday luncheon I met a Captain of Engineers who had just returned from France. He was a red-headed American boy and was one of that bunch that held the Hun with only pick and shovel and revolver for many hours—until many were dead and a few were succored by the Regulars. He told us about the barrage, and how much easier it was for an officer who was walking about and looking after his men than it was for the private who could only hug the bottom of the trench and wait until it was over. When this chap tried to pull a pipe from his kit bag, a soiled and broken cardboard box fell out and spilled a French and American Cross of Valor on the floor.

Some months back a nitric acid plant was shut down for want of men. You all know what a charming job it is to feed nitrate of soda into hot apparatus amid choking fumes during a hot and stifling day or night. The men could get much more agreeable work in the ship yards a few miles away. More and more pay was offered until the rate was extravagant, but no men wanted it. Then the superintendent called a meeting of the men and explained what nitric acid meant in the war program, and asked for volunteers. About five or six men answered, and "carried on," and during the next week they got five more, then that crowd got ten more, and so on. That plant has been running full ever since, and to my mind those chaps are just as deserving of the praise and gratitude of our nation as the man who goes over the top over there.

If I have said anything which any of you do not like, I am sorry. If I have said anything which will help you or others, then I can only add, "Carry on."

\*Chemists' Club, Oct. 25, 1918

## Gas Warfare, Both Offensive and Defensive

An Account of the Progress Made in the Development of Gas Warfare Since the First German Attack at Ypres on the Canadians—Lethal and Neutralizing Types of Gases—Containers, Shells, Grenades—Types of Masks

MAJOR H. W. DUDLEY, R.E., of the British-American Anti-Gas Service delivered a lecture on "Gas Warfare, Both Offensive and Defensive" at the first meeting of the season of the New York Section of the Society of Chemical Industry, held at Rumford Hall in the Chemists' Club, Oct. 25, 1918. Major Charles E. Sholes, the honorary chairman, presided.

Major Dudley introduced the subject by saying he had spent some time with American troops in France while they were in contact with British troops, and he took pleasure in saying that he found, without exception, the soldiers of each nation filled with great admiration and respect for those of the other and that the fullest co-operation has existed between the British and American armies in regard to gas warfare.

Although gas warfare is but one year old in the United States, there are already, all over the country, great works established for the production of gas munitions, and all of the many developments brought out here are offered immediately to the British army. He desired to lay special emphasis upon the evidences of good will in this respect that had come before him. Only a short time ago a gentleman engaged in making gas warfare material in this country had written him that he understood the English were having trouble with a certain feature of a necessary process. He added that it had been his good fortune to overcome the difficulty and he offered his entire research and practice to the British Government in the interest of the common cause.

The development of gas warfare has been somewhat like the old game between the armor plate and projectile

manufacturers in that it has involved a constant race to get ahead between offensive and defensive. All nations have long known its possibilities, and at the Hague Convention in 1899 it was agreed that poison gas should not be used in war. The Germans broke the convention and delivered their first attack on April 22, 1915. It is interesting to note, however, that whenever any act of extraordinary villainess was perpetrated by the Germans there was likely to be some accompanying propaganda. Thus there appeared an official German communiqué in July of this year, when they expected to succeed, that gas warfare originated with the British Admiral Donnell. The reference is probably to a British admiral of that name who was born in 1775 and died in 1860, and his entire record in relation to the subject was his caution to his Government that asphyxiating gases could be used in warfare. Again, before they made their first attack there were charges brought in official German army communiqués that the English were using poison gas against German soldiers, claiming that this had been done as early as March 1, 1915. The purpose was evidently to prepare the home conscience as well as that of neutrals for the proposed innovation. The first British gas attack actually did take place in September, 1915, and not before. There is every reason to believe that the Germans now bitterly regret that they ever began it, for it is evident that the morale of their army has suffered under it. Captured letters indicate their genuine fear of it and *Die Vossische Zeitung* has published eloquent jeremiads on the subject. And if they only knew what is now being hotted up for them they would grow even more sore depressed.

Enormous amounts of gas are necessary, which limits the substances which can be used. They must be easily prepared and so plentiful that by constantly threatening the enemy with them his efficiency is impeded.

#### FIRST ATTACK WITH CHLORINE

The first attack was with what is called the cloud method, near Ypres on April 22, 1915, with chlorine. It was carried in cylinders containing about 44 lb., and these were provided each with a siphon, extending to the bottom, through which the gas, when liberated, escaped through a valve at the top. The siphon provided for the regularity of escape and the cylinders emptied themselves in about three minutes. They were placed in holes before the trenches and covered over so that they might not be detected. To make the attacks more effective toward the end of 1915 the Germans added about 20 per cent phosgene (carbonyl chloride) to the chlorine.

The method has limitations and has been largely, but not wholly, abandoned. It is effective only under favorable weather conditions with the wind blowing in the right direction and at the desired velocity. To be entirely successful it is necessary that the enemy have defective respirators or none at all, although even with good protection and good discipline there are always some casualties in a cloud attack. The Russians, for instance, once had some 10,000 casualties from a comparatively small amount of gas, due to inadequate preparation. In captured German documents it was recorded that their pioneer gas troops liberated 3600 tons of gas and killed 35,000 men with it. Whether this is true or not, it is well to remember that the behavior of the Canadians in holding the line near Ypres and putting up at least enough defense to keep the Germans back when this kind of warfare was considered unbelievable, when they did not know what it would do to them or whether more was coming or not, and when they had no defense against it, was one of the greatest and bravest achievements in this or any other war, and it undoubtedly saved the Channel ports.

There are not many gases suitable for cloud attacks. A suitable gas must have a low boiling point to force itself out of the cylinders, it must have high density to give it adequate covering quality, and it must be stable. Chemically active gases have been found easy to defend against in cloud attacks, whereas those that are chemically inert present greater difficulties. Referring again to the relation of gas clouds to the wind, Major Dudley recalled that in April, 1916, about a year after their initial effort, the Germans released a cloud against the British in a light easterly breeze. Just as the cloud was formed the wind shifted and blew the gas back over the German trenches and caused them 1500 casualties. There is one little detail that the Germans neglected to provide for in their gas offense: the prevailing winds on the western front are from the west. This inadvertence on their part has not been remedied even to this day. Another difficulty is that whereas high concentration is required, the highest concentration is in the immediate neighborhood of the trenches of the offensive side and, of course, the gas constantly diffuses.

Casualties depend upon the success of the following three elements:

1. Surprise. Cylinders must be put into place secretly

and hidden. It is a great help to the enemy to know that a cloud attack is to be launched against him with the next fair wind. Escaping gas also makes a noise and gives an alarm.

2. Penetration of the hostile respiration. This is theoretically possible and can be realized, actually, on a limited scale.

3. Exhaustion of hostile respirators. This is theoretically possible but practically, owing to the enormous quantity of gas required to neutralize the chemical filling of a modern respirator under field conditions, the method of producing casualties is unattainable.

When the high and really (*wirklich*) privy councillors of the All-Highest (of whom Professor Nernst is said to have been a leader in the gas business) discovered that the timorous English and decadent French did not give in to their clouds of terror, the next and obvious thing to do was to fill shells with gas. The first gas-filled shells were employed in an attack against the French on May 15, 1915, which was the second step in gas warfare. With shells a wider range of gases is available. Two main types are in use, of which one is lethal and the other is called "neutralizing," the idea of the second being to hamper the opposing army and to put its men, at all events for the time being, out of action. They began with what are called lachrymators, or tear shells. These cause temporary blindness, among other disqualifications. The first German "T-Staff" (used in May, 1915) was a mixture of xylyl and benzyl bromides. Another lachrymator was "B-Staff," or brominated methyl-ethyl-ketone, and still another was "Green T-Staff," which was a mixture of xylyl bromide and bromacetone. A high concentration of these gases produces nausea and Major Dudley has seen persons made unconscious by it.

Another class of neutralizing, as distinguished from lethal gases, is known as the sternutators, or, as they are commonly called, sneeze gases. German shells of this sort are marked with a blue cross and contain diphenylchlorarsine (a solid), mixed with a high explosive which scatters it in fine particles and causes sneezing and vomiting; the purpose being to make soldiers remove their masks and then follow up the attack with a lethal gas.

Lethal gas shells were marked with a green cross and at first contained monochlormethylchloroformate, which was "improved" by substituting trichlormethylchloroformate, sometimes mixed with phosgene, and this remains the German prime favorite. The mixture is very toxic. Sometimes it produces a delayed action so that men fall down and die a few hours after they have been gassed if they indulge in vigorous exertion.

#### THE "MUSTARD" GAS

Another discourager of irreverence toward German might and will is an eye, lung and skin irritant which bears a yellow cross upon the shells containing it, and for this reason is called mustard gas. It is a liquid that boils at over 200 deg., has low vapor pressure and is heavier than air. Mustard gas is dichlorethyl sulphide. It has but a faint, garlic-like odor and at first troops were deceived by it. To disguise the odor sometimes a little prussic acid is added and again sometimes trichlormethylchloroformate (or "diphosgene") mixed with chlorpicrin or other lachrymators. One part in 50,000

for two minutes will produce severe conjunctivitis, but this is almost the least of its evils. It is a real torture gas because, in addition to its painful effect upon the eyes, it is an intense skin poison, producing sores that easily grow septic and which are in their nature very like burns. Parts of the body that are moist with perspiration are especially susceptible to it and its effects, while not immediate, are sure and put men completely out of action. Men gassed with "mustard" are likely to be attacked under the armpits and in the crotch as well as on the hands, and the effects are exceedingly painful. Still another sequel of this poison is within the lungs, where the same kind of blistering action takes place, with pneumonia and tuberculosis frequently following. Owing to its high boiling point, if the weather is cool and calm it may cover a locality for a week or more. Sometimes again it will be apparently inactive during a cool night, but as soon as the sun

when the first attacks were made. Fighting with poison gas was one of those things that under agreement was not to be done, and the matter was considered as settled. But it wasn't. All manner of expedients were availed of at first, from handkerchiefs and socks filled with moist earth to anything else that could be thought of. The women of England and France were appealed to and provided the soldiers with respirators in the form of veils enclosing a handful of cotton wool which was dipped in a solution of sodium thiosulphate ("hypo"), sodium carbonate and glycerine immediately before using. Within three days about 1,000,000 such respirators were made in England. In the case of one British army a new respirator was devised and the women in the towns immediately behind the front were requested to make a supply. Material was rushed from Paris by every car available and within a few days those French women had provided 80,000 of the new respirators which were in use in the line of battle. The original veils were reasonably effective against chlorine, but were difficult to operate in the trenches owing to the need of keeping the soaking fluid everywhere convenient. An improvement became imperative as soon as the Germans began to use phosgene.

A respirator should be simple in design and easily adjusted. It is also important that it consist of one piece. The first improvement over the veil was the "hypo helmet," made of flannel, treated with sodium carbonate, sodium thiosulphate and glycerine in solution, and provided with mica windows. The skirt was tucked in under the collar and while it was rather unpleasant to wear it saved many thousands of lives. The next type was called the P. helmet and consisted of a bag made of (cotton) flannelette impregnated with an alkaline solution of sodium phenate. This development was made necessary by the introduction of phosgene into gas warfare. The mica goggles were unsatisfactory and were replaced with glass and a respiratory valve was added through which the breath is exhaled but through which it may not be inhaled. The protection against phosgene was later improved by adding hexamethylene tetramine to the impregnating solution. With these improvements it became known as the P.H. helmet.

#### METHODS OF PROTECTION

The introduction of inert gases made an entirely new method of protection necessary, for the flannelette filter was not adequate. This brought about the canister through which the breath is inhaled and blown out through the special valve. In the masks now in use by the British and American armies the nose must be clipped shut, and it goes without saying that the wearing of such a device for any length of time is very uncomfortable. At times, however, it has been necessary for men to wear them for as long as twelve hours at a stretch. The facepieces of rubberized cloth are made full so as to be used to wipe off the interior of the goggles, which become clouded from the wearer's breath.

Strangely enough, although the Germans were the first to use poison gas, they were not prepared to defend themselves against it when it was hurled back at them. Their masks contain a drum of charcoal screwed on before the mouth and both inhalations and exhalations are made through it. The lack of an exhalation valve is

FIGS. 10 AND 11—TYPES OF GAS CONVEYANCES. GRENADES, SHELLS AND BOMBS

shines upon it in the morning it becomes effective. It is used in enormous quantities by the German army and in all sizes of projectiles from a capacity of 300 to 400 cc. to 11 liters.

Hand grenades are in frequent use. They contain smoke producers and toxic gases for cleaning up dug-outs. It is a very useful minor weapon, and some are equipped with a device whereby a rod may be attached and the whole shot from a rifle by means of a blank cartridge. They may be called chemical ferrets and are used by the allied armies. It is much safer to throw one into a dugout than to make a personal exploration, and they have been found very persuasive among hiding boches. Later developments provide for firing gas shells of very large capacity from mortars. Gas is not used in aeroplane raids.

In regard to gas defense it should be borne in mind that there wasn't any at the beginning of the war or

a serious defect, but the drum is a clever device and has been adopted in some American and some French masks. The German facepiece was first made of rubberized cloth but later of softened leather bound with tape, and in the place of rubber bands for adjustment, cloth tubes containing wire springs were used.

## Sodium Sulphide and Other Products from Nitre Cake

By H. P. BASSETT, PH. D.

THE disposal of nitre cake, one of our large waste products in the chemical industries of this country, has for many years been a source of much investigation.

This waste product from the manufacture of nitric acid has often in the large industries, like the powder companies, been hauled out to sea and dumped, while at inland plants it is buried, when it remains for a considerable length of time, finally leaching away. These two sources of disposal are the ones generally used, as the laws of nearly all our states do not permit it being dumped into the streams, because in many cases the streams furnish water supply for cities; also, it destroys the fish in such streams.

Aside from the difficulty of disposal, there is much value lost in this material, as it contains 30 to 31 per cent free acid besides the sulphuric acid combined as normal sulphate. Of late years considerable amounts of nitre cake have been used in the glass trade and for the separation of iron and nickel, but the normal sulphate is preferred, as the acid sulphate is detrimental to the furnace linings and the free acid given off as sulphur dioxide causes damage to the vegetation.

The normal sulphate can be made from this material by neutralizing with lime and then evaporating the solution of normal sulphate, but considerable amounts of lime or limestone are required, and salt cake made in this manner is expensive and in normal times does not pay the expense incurred. However, the expense in this method may be decreased if special precaution in neutralizing, like a counter-current system, is used and the calcium sulphate obtained in a fair degree of purity, when it would have a market value as a filler for paper, in the cement industry and for many other uses where shipping facilities were adequate.

The second method is to form normal sodium sulphate and either hydrochloric or nitric acid. This can be accomplished at a temperature of red heat and a very high grade sulphate obtained if the material is very intimately mixed and a proper furnace used for carrying out the reaction.

The third method is a unique one and its commercial value would have to be determined. This method consists of mixing the nitre cake with pyrites cinder and roasting the mix at about 600 deg. C., when the free acid is evolved as sulphur trioxide, which can be absorbed in other sulphuric acid to form fuming acid, which commands a good price even in normal times. The cinder from this operation consists of iron oxide and sodium sulphate, and on leaching the sodium sulphate can be recovered.

The two last methods of course have their advantages in that the free acid is used up in making nitric or hydrochloric or sulphuric acids, which are either used

by the industries having this material for disposal or in allied industries. They have the disadvantage, however, of probably overloading the market with salt cake, and other avenues would have to be opened up for this material. This salt cake, of course, could be used in the manufacture of sodium carbonate by the Le Blanc process. But again we have a waste material—calcium sulphide—which is as bad as or even worse than the original nitre cake on account of the odor.

The problem finally develops into the disposal of the sodium sulphate or salt cake. A limited amount could be sold to the glass and nickel industries, but a very important market could be found in the sale of sodium sulphate, which can be obtained very economically from this material. This market also has the advantage of growing larger as the supplies become available. The two large uses at present are in the leather trade and in the flotation processes.

Much work has been done in this line with varying results. Berzelius obtained sodium and potassium sulphites by reduction of their sulphates in a current of hydrogen. Berthier obtained them by reduction with carbon. Many attempts have been made by Claus and others to make use of Berthier's method for the production of sodium sulphide, but unsuccessfully. In their work they obtained products which contained thio-sulphates and carbonates due to oxidation by the air in their process of manufacture. This, however, can be avoided by using carbon in the form of bituminous coal where volatile matter is given off to keep the furnace full of a reducing atmosphere and carrying the reduction out in a design of furnace which can be kept air tight. It has always been considered this reaction required a high temperature, but in my work I have found that 96 per cent of the sodium sulphate can be obtained in the form of sulphide at a temperature not to exceed 650 deg. C., which can be easily maintained in a cast- or wrought-iron tube furnace.

At high temperatures the sulphide will attack the iron or even many kinds of brick, but at this low temperature it attacks the iron only slightly, forming in time a thin black scale of an iron sulphide when the reaction ceases. This, however, will scale off if the furnace is suddenly cooled or heated, but by gradually cooling or heating the furnace, the greater part of the scale will adhere and the tube last for months for this operation. In a rotary type of furnace the tube may also be made in sections and when one section wears out it can be easily replaced. It might be of interest to state that this scale mentioned above forms only at the hottest part of the furnace, which, as stated, never exceeds 650 deg. C., consequently this section would be the only one needing replacing.

The carbon added to the sulphide is in excess of that required for the reduction, and consequently the cinder will contain some unused carbon and require leaching and crystallizing to recover the sulphide in marketable form. It might also be stated that means must be provided for cooling the material as discharged from the furnace out of contact with the air.

Other products may be made from nitre cake, as sodium sulphide and the like, but it appears to me that the manufacture of the sulphide, owing to its increasing demand, would go a long way in disposing of what now is one of the largest waste products we have.

# Nitrogen Fixation Furnaces\*—I

## A Review of the Various Types of Arc Furnaces, with Details of the Kilburn Scott 3-Phase Furnace—Balance of Current Phases, Size and Starting of Furnaces—Radiation and Cooling-Water Losses—Electrodes

BY E. KILBURN SCOTT

Arc furnaces for fixing atmospheric nitrogen differ from arc furnaces for making alloys, carbide, etc., in that instead of the electrodes being of carbon they are made of special metal which wears away very slowly. Also, the potential used is several thousand volts, which necessitates better insulation. Another difference is that air only is used or charged; the internal construction is therefore simpler as regards the refractory lining, for there is no melted metal or flux to react with or to cut the brickwork.

The furnaces are especially suited for intermittent working with off-peak power, because they can be started and stopped at any moment with almost the same facility as an ordinary arc lamp, and there is no fused material to be run off or to freeze in case the electricity fails; also, after starting up again, full yields are obtained very quickly. The furnaces may therefore be advantageously installed wherever cheap 3-phase power is available for say sixteen or twenty hours a day. The arc process is the only method for fixing atmospheric nitrogen that can be so used.

A convenient size of air nitrate factory is one to take about 10,000 kw., but of course the larger the factory the lower the cost per kilowatt of plant installed and the lower the working cost and of overhead charges per unit of finished product. The ordinary standard voltages of 5500 and 6600 and periodicities of 25 and 60 per second are suitable, so it is not necessary to install special generating machinery. The energy can be tapped from a general transmission network, although there are advantages in having the factory near to the power house.

To combine nitrogen and oxygen efficiently by electricity it is necessary to obtain as intimate contact as possible between the gases and the arcs, and various features which more closely approximate to this requirement are discussed in this paper; further, in order to emphasize certain points, comparisons are made of types of furnaces, especially those which produce the arcs in different ways. For the purpose of discussing types of furnaces, they can be classified as follows:

- (A) Designs having mechanically movable parts.
- (B) Designs employing a magnetic field to direct the arcs.
- (C) Designs depending on air currents only to direct the arc.

### DESIGNS HAVING MECHANICALLY MOVABLE PARTS

The Bradley and Lovejoy apparatus as it was installed at Niagara Falls is historical but nevertheless interesting, because it is a distinctive type. It de-

pended on the formation, prolongation and interruption of many thousands of sparks or arcs per second, each one separate from the rest. The arcs were produced by rotating an iron cylinder fitted with platinum points inside a fixed enclosing cylinder having an equal number of points. Direct current at 10,000 volts was employed, partly because the apparatus was built at a time when that form of current was generally in use. It was afterward appreciated that it would have been better to work with alternating current.

MacDougall and Howles, who were working on the problem in England about the same time, employed alternating current, and the writer gave them assistance, especially in showing how the arcs could be stabilized by reactance.

Another design depending on mechanical movement is that of J. S. Island of Toronto; see Fig. 1. There are in this furnace four V-shaped rings, two of which rotate, and the electric arc which would normally remain stationary at the shortest gap is drawn around. To the eye it looks like a ring of flame, but in reality it is a single arc rotating rapidly round the annulus. Air passes through perforations in the apices of the stationary rings, and at first sight this would appear to be a good plan. The writer's experience, however, is that such holes are subject to excessive burning.

The Rankin furnace, to which T. H. Norton draws attention in an article in the September, 1917, *Scientific American*, has been tried in California. It is a distinctive type because the arcs are mechanically caused to move through the air, instead of the air being blown through the arcs. The sparking points are fitted in a sort of piston which reciprocates in a cylinder and at the same time is rotated to and fro by a thread on the spindle. Current is led to the sparking points by wires through the hollow spindle.

As general comment on the above, the writer considers that designs depending on a number of electric sparks or arcs which are at relatively large intervals apart must necessarily allow considerable quantities of air to pass without contact. Further, designs which require constant mechanical movement of parts are obviously at a disadvantage when compared with those referred to below, which do not require moving parts.

### DESIGNS EMPLOYING A MAGNETIC FIELD

The Moscicki furnace, used in Switzerland, has a magnetic field which causes the arc to rotate around an annular opening. Referring to Fig. 2, there is a reaction chamber with an air chamber below, both of which are surrounded by water. The annular opening is formed between a high tension electrode and the lower edge of the reaction chamber, which latter is

Fig. 6—Modification of Pauling design due to Phaecler and Heckenbleckner.

earthed. Magnet coil *D*, acting in conjunction with the steel construction of the furnace, sets up a magnetic field across the annular opening which causes the arc to rotate. It can, however, only be at one point at any one moment, whereas air passes through the whole opening all the time; it therefore follows that a large proportion cannot contact with the revolving arc.

The Birkeland-Eyde furnace, used in Norway, France and Spain, has also a magnetic field, but in this case it forces the arc into two half discs of flame, which alternately rise and break in the top half and in the bottom half of the reaction chamber. The electrodes, see Fig. 3, are of copper tubes supported on ball insulators, and they project into a circular reaction chamber, the side walls of which are pierced by a large number of small holes. Air passing through these holes strikes into the flame at right angles, and obviously at any moment only half the volume can enter on the side on which is the arc.

The arc constantly rises and breaks, and, further, many of the holes are near to the edge of the reaction chamber. A large proportion of the air, therefore, fails to make contact with the arcs. As further general comment on those furnaces which depend on a magnetic field to direct the arc, the writer is of opinion that they are at a disadvantage compared with those mentioned below, which use air only, because of the expensive magnet steel construction which interferes with accessibility, the cost of copper magnet coils and the cost of dynamo electric machinery necessary to provide direct current to excite the coils. Another reason is that an extra circuit is required, with instruments and regulating switches, etc., in order to adjust the strength of the magnetic field to suit the velocity of the air.

#### DESIGNS DEPENDING ON AIR CURRENTS

In the Schoenherr furnace, as used in Norway, air is blown tangentially into the bottom of a vertical reaction tube made of steel, and in passing upward with

is only a small fraction of an inch; therefore much of the air whirls past without coming into intimate contact with the standing arc. A point of interest in this design is that it has a special air preheater combined with it. This takes the form of annular tubes, as shown in Fig. 4, through which the hot gases and the air pass in contra-flow directions.

The Wielgolski furnace, used by the American Nitrogen Products Co. of Seattle, Wash., has also a standing arc, but instead of being similar to a single straight rod it is in the form of a "bight" having its ends springing from electrodes at the bottom. For a given voltage, the height of the arc is therefore considerably less than in a Schoenherr furnace. Each electrode is a water pipe bent into a ring and air passes up through it.

The Pauling furnace, used in Italy, Austria and Germany, has a fan-shaped arc flame which forms between horn-shaped castings. Below the electrodes

FIG. 8—COMPARATIVE CURVES OF 3-PHASE AND SINGLE-PHASE

there is an air pipe having a narrow slot, the idea being to get as much air as possible into the flame, but as a matter of fact it spreads out in all directions, as indicated in Fig. 5. Fig. 6 shows a modification installed at Nitrolee, S. C., and due to R. Phaehler and I. Heckenbleckner. Each electrode is supported at the bottom only, and the cooling water enters and leaves at that point, experience having shown that an upper connection causes short circuits and is difficult to insulate. Air is blown through two nozzles, the inner one passing a relatively small quantity at high pressure so as to cool the kindling blades. The bulk of the air, which is preheated, passes through the outer nozzle at low pressure. The power is therefore less than would be the case if all the air were at high pressure. Each side wall between the electrodes and just above the zone of maximum heating has a duct through which gases from the furnace, which have been cooled down, are blown. The object is to cool the highly heated nitric oxide below the critical temperature of dissociation, and as the return gases contain practically the same percentage of nitric oxide gas as the freshly treated gas there is no dilution.

#### THE KILBURN SCOTT FURNACE

Furnaces which work with single-phase alternating current have to be used in sets of three on a 3-phase supply, whereas the Kilburn Scott type now to be described in greater detail uses all three phases in a single reaction chamber.

As shown diagrammatically in Fig. 7, it has three wedge-shaped electrodes arranged with intervening re-

FIG. 7—DIAGRAM OF KILBURN SCOTT 3-PHASE FURNACE

a whirling motion it maintains a rod-like arc in the center. To distinguish this arc from those of other furnaces, the writer calls it a "standing arc." The cross section of the reaction tube, see Fig. 4, is about 30 sq.in. (190 sq.cm.), whereas the section of the arc

fractory material so as to enclose a 6-sided conical space, having its apex at the bottom. Three-phase current supplied to the electrodes produces a combined arc which is flared out by the air, and with 60 periods gives 360 flames per second.

By drawing three sine curves with a phase displacement of 120 degrees, as in Fig. 8, it is seen that current is always flowing in the reaction chamber, and it can be shown mathematically that the electric energy varies between 0.86 and 1.0. On the other hand, with the single phase the energy varies from zero to maximum, and twice in each cycle there is no current.

The flame appears to the eye like a double cone having one apex at the bottom, where the electrodes are nearest together, and the other at the top, where the flame tapers off. The flames flicker about with great rapidity in different planes, and so are constantly intercepting fresh particles of air. Fig. 9 indicates how it

FIG. 9—DIAGRAM SHOWING ROTATION OF 3-PHASE ARC

revolves, the speed of revolution corresponding to the frequency. If we assume 60 periods per second, then as it takes longer than one-sixtieth of a second for air to pass up the reaction chamber, it follows that practically every particle must come into the arc field.

From the point of view of the supply of electric energy, it is desirable to have all three phases balanced, and this is especially necessary when current is purchased from a public supply company, for the general supply must not be affected by low power factor and unbalanced and variable loads.

When single-phase furnaces are connected to a 3-phase supply, there may be considerable lack of balance due to one furnace dropping out of circuit; also at starting up, unless all the furnaces are switched in together. If one arc fails, there is a possibility that the circuit breakers of the other furnaces may trip, with the result that a heavy load is suddenly thrown off and a surge may set up.

The 3-phase furnace gives no trouble in this way, for it functions as a single unit and the phases balance automatically. Even if deliberately set so that they do not balance, they tend to equalize by burning at those points where current is greatest. There is very little chance of a 3-phase furnace failing altogether, because the three phases help to maintain one another.

#### STARTING UP THE FURNACE

As the electrodes of nitrogen fixation furnaces are of metal and work at high voltage, they must not be brought into contact. Starting is usually effected by carefully moving the electrodes until they are near enough for current to jump across. After running until the interior has become heated, the electrodes are withdrawn to the regular working distance. Adjustment must be made carefully to minimize rush of current, and as this depends on the furnace attendant,

the amount of reactance in circuit has to be sufficient to allow for the contingency of careless operation.

The Schoenherr furnace is started by means of a lever which is moved by hand until it is near enough to the lower electrode for the current to jump across. The lever is then withdrawn and the whirling air carries the arc to the top of the reaction tube. If the arc fails, which is fairly frequent, it has to be rekindled by hand, so considerable attention is necessary.

Pauling uses the device shown in Fig. 10, which shows two furnaces connected in series in each leg of the 3-phase supply and an auxiliary transformer connected across one pair of electrodes on each series. The high tension coil of this transformer gives a voltage several times greater than the main supply, and the arcs are kept going by the higher voltage set up by current shunted through the primary coil.

While experimenting with an early model of the Kilburn Scott (K. S.) 3-phase furnace, it was found possible to use pilot or trigger sparks to break down the air dielectric and thus dispense with movement of the electrodes for starting. This is a simple solution of the problem and does away with uncertainty of operation by an attendant. A wire placed midway between the three electrodes just above the central air nozzle is connected to an extra high tension supply, which causes sparks to jump from the wire to the electrodes, thus ionizing the air and causing the main current to flow. The more pilot sparks there are in a given time the better the effect; also, the higher the frequency the less the air resistance. The two circuits work together in much the same way as when telephone and telegraph messages are carried at the same moment through one set of conductors.

With pilot sparks to break down the air dielectric between the three electrodes, the full value of the current wave is utilized and the curve approximates

FIG. 10—PAULING FURNACES IN SERIES ON EACH PHASE AND STARTING TRANSFORMERS

to a sine wave. On the other hand, with single phase the voltage has to rise to a certain amount to overcome resistance and cause current to flow.

#### SIZE OF FURNACE

A 3-phase furnace is better than three single-phase furnaces aggregating the same power, because there is only one piece of apparatus to attend to and the cost is at least halved; also the space occupied, inclusive of passage way around the furnaces, is less.

As a 3-phase arc flame increases in three dimensions with increase of power, it follows that kilowatt capacity goes up very rapidly with increase of size. Usually

in mechanical designs doubling the linear dimensions will theoretically increase the capacity eight times, but a 3-phase furnace for nitrogen fixation increases in much greater ratio.

Speaking generally, the larger a furnace the more accessible are the interior parts and the easier it is to adjust and renew the electrodes. Radiation losses are also relatively smaller, and the percentage of energy absorbed by the reactance coils being less, the power factor tends to be higher.

The Schoenherr design is limited to about 1000 kw., because the length of the reaction tube is governed by the voltage, while at the same time the current that can be dealt with from a single electrode is limited.

FIG. 11—CHARACTERISTICS OF ARC AND ALTERNATOR

FIG. 12—FALLING AND RISING CHARACTERISTICS OF ELECTRIC ARCS

Again, the amount of air that can be passed through a reaction tube at a given velocity is limited, so in order to increase output a larger diameter tube would have to be used, thus giving greater clearance around the arc.

Birkeland-Eyde furnaces are now built with a capacity of 4000 kw., which is about 20 times larger than those made some twelve years ago. They are essentially a single-phase design. During the same period, carbon-arc furnaces for making alloys and for carbide have increased in a much greater ratio, and they are all now made for multi-phase working.

#### RADIATION AND COOLING-WATER LOSSES

In the Schoenherr furnace, radiation accounts for 17 per cent and the electrode cooling-water for about 30 per cent. It is therefore desirable to design electric furnaces with as small radiation surface as possible and with a minimum of electrodes through which heat can pass to the outside air.

Radiation loss varies directly as the wall area of the furnace, and cooling-water loss may be said to vary with the number and the size of the electrodes. Two electrodes being the least that can be used for any one furnace, it follows that three single-phase furnaces must have six electrodes while a 3-phase furnace of the same total power has only three.

Three electric arc flames acting together in one closed space will give a higher average temperature than the same arcs each at some distance apart and within separate walls each radiating heat. That is to say, a 3-phase furnace of 3000 kw. will have less wall area and therefore less radiation than three 1000-kw. single-phase furnaces; also the heat absorbed in cooling three electrodes of one furnace will be less than for cooling six electrodes of three separate single-phase furnaces.

Doubling the number of electrodes means doubling the pipe connections and fittings, also electric cables,

etc.; and as the water connections must necessarily be connected to the high tension supply, it is an advantage on this account to have as few as possible.

In furnaces with diverging electrodes, heat is principally generated about one-third the way from the bottom, so the cold water should impinge at about that point in order to keep the metal from being worn too rapidly. At the same time, in order not to reduce the temperature of the reaction chamber too much, it is necessary to adjust carefully the amount of cooling water.

#### ELECTRODES

The writer's conception of a blown-arc flame is that it consists of arc threads or streamers, which strike across the bottom of the electrodes and then, acting like flexible conductors, are carried up by the air current. The ends move rapidly over the surface of the electrodes until the arcs have reached the maximum length at which the voltage will sustain them, when they snap suddenly and new arcs are started.

If the formations and extinctions of the arc threads synchronize exactly with the alternations of the electric current, then the furnace is working smoothly, and it is easy for those accustomed to such furnaces to know this by the sound.

Around each arc thread there is a flame of burning nitrogen, and as nitric acid forms it diffuses away into surrounding air and in so doing becomes cooled. Probably the quickest chilling takes place at the moment when each arc-thread breaks. The arc also tears particles of metal from the electrodes, and these, becoming

FIG. 13—DEVICE FOR STABILIZING THE ARCS OF BIRKELAND-EYDE FURNACE

incandescent and oxidized, may play some part in expediting or retarding the reaction, for it is known that some metals are better than others from the point of view of yield of nitric oxide.

With diverging electrodes, the ends of the arcs travel along the surfaces in leaps, which is possibly due to softening of the metal, and the arc is momentarily held at each point until pressure of air (or the magnetism in the Birkeland-Eyde furnace) overcomes the adhesive tendency. When the surfaces of electrodes are large, the wear is relatively slow and the electrodes need renewal only at long intervals. On the other hand, when the arcs spring from the end of an electrode, as in a Schoenherr furnace, burning is intensive and the electrode has to be fed forward regularly.

The electrodes must be of dense metal having high melting point and not readily oxidized; also it should be a good heat conductor so as to pass heat quickly to

the cooling water. Steel is used in the Schoenherr and Moscicki furnaces, but it is not a good metal because the magnetic oxide of iron to which it burns may be carried over to the absorption towers and stain the acid. Steel begins to oxidize at about 370 deg. C., and oxidizes rapidly at about 500 deg. C. Nickel has an ignition temperature of about 650 deg. C., but it is too expensive to use, and this remark also applies to many metals and materials which have high melting points—platinum, for instance. Those working on the nitrogen fixation problem are always on the lookout for better electrodes.

In this connection, the process called "calorizing" is of interest, because it raises the oxidizing temperature. The process depends on the fact that at high temperature and in a neutral atmosphere powdered aluminium will enter into combination with a metal and form a homogeneous alloy which cannot be destroyed except as part of the mass of which it is part. Depth of the impregnation depends on the length of time of treatment, and by it the oxidizing temperature of steel can be raised to over 1000 deg. C.

Copper is a good metal to use for electrodes, because it is easily made to the required shape and wears away smoothly without releasing troublesome vapors. After a run with some copper electrodes which were fixed by steel screws, having their countersunk heads in line with the path of the flame, it was noted that the steel was considerably burnt, whereas the surrounding copper had only slight surface marks.

It is important to minimize the oxidation, because when a considerable amount of electric energy is employed in vaporizing metal, then there is so much less energy for exciting the gas molecules and bringing about the nitric oxide reaction.

Birkeland-Eyde furnaces use tubes of pure electrolytic copper about 2 in. (5 cm.) in diameter and  $\frac{3}{16}$  in. (5 mm.) thick, bent into the form of a U, each leg of which is about 8 ft. (2.4 m.) long.

Electrodes of copper alloyed with other metals have been used to advantage, and those metals which show good nitrogen bands in the arc spectrum are obviously the better ones to employ.

There is some reason to suppose that the presence of metals or oxides of metals act in a catalytic way in increasing the velocity of the reaction. The action of a catalyst is supposed to be such as to make it unnecessary to use higher temperature to get a workable velocity.

For smooth electrical operation it is important to have the arc stabilized, and this is the condition which gives good yields of nitric oxide. Further, it is important to have the furnace working easily, because of the effect of an unstabilized arc on the supply circuit. An ordinary arc lamp works well, because the carbons are automatically moved so that the distance between them increases with current, to effect which an electro-mechanical device is used. This is possible because the parts to be moved are small and of light weight, but obviously the heavy metal electrodes of large electric furnaces and the large power involved present a much more difficult problem.

The resistance of an alternating arc varies with current in such a way that when the voltage between the electrode decreases the current then increases. In

other words, the characteristic of the arc is a falling one, as shown by curve *aa* of Fig. 11. If the voltage of supply can be made to fall in accordance with the arc characteristic, then complete stability of the arc is obtained, but to do this the only way is to specially design the alternator for a large voltage drop, as shown by curve *bb*. The writer has used such an alternator with good effect, and it is of interest to note that the latest installation in Norway, at Rjukan II, has alternators with large voltage drop, each supplying a group of three single-phase furnaces of 4000 kw.

When an air nitrate factory receives energy from a transmission line so that step-down transformers are required to reduce the voltage to that required by the furnaces, then reactance may be embodied in the transformer. The transmission line itself and the various connections, etc., also give some reactance, which goes toward reducing that necessary in the separate reactor.

It is obviously desirable to design a furnace so as to work with as little reactance as possible, and one way is so to design the electrodes that they require little or no adjustment, for obviously reactance must be larger if the contingency of inexpert adjustment has to be met.

Stabilizing an arc against what may be called abnormal conditions may be done by automatically varying the force of the air in accordance with current in the arc, for increased air pressure increases the arc voltage. With varying air pressures the arc characteristic will move out parallel to itself, as shown in curves *bb* and *cc* of Fig. 12. An automatic device may be employed to do this, so giving the equivalent of a rising characteristic, as shown by the curve *a*, *b* and *c*.

F. G. Lilienroth has suggested such a device, and for a Birkeland-Eyde furnace (see Fig. 13) he provides a regulating switch in the field-magnet circuit, which switch is varied by a solenoid through which passes the current of the electrodes.

(To be concluded)

### Restoration of Belgium

At a recent meeting of the New York Section of the Society of Chemical Industry a resolution, introduced by Dr. Jerome Alexander, was passed which, after reciting that Germany had deliberately stolen, destroyed or carried away machinery and property in occupied territory and had deported or destroyed communities of skilled artisans, all for the purpose of permanent economic injury of competitors in the world markets, read as follows:

*Be It Resolved*, That the New York Section of the Society of Chemical Industry requests that the proper authorities of the various allied Governments take special note of the above facts and insist that Germany, where possible, be compelled to restore the stolen machinery and other property, or replace the stolen property and also whatever machinery or property has been destroyed, by equivalent machinery or property taken from German factories; and that they furthermore see to it that all allied industries are fairly and justly safeguarded under the ultimate terms of peace against the machinations of an insidious and conscienceless enemy, whose express intention is to reduce other nations to industrial subservience and dependence.

## Future of Pure and Applied Chemistry\*

Account of the Political Aspects of Chemical Science in the British Empire — Retrospect on Conditions Prevailing at the Start of the War and the Sudden Changes That Were Brought About Thereby

By WILLIAM JACKSON POPE

FOR THREE years pure chemical research has been dormant the whole world over, and it would be difficult for the most accomplished essayist to arrest attention for an hour by an address on a subject of purely academic interest. Our mental point of view and our outlook upon both present and future are entirely different from those of four years ago; although the present is obscure and painful, the future gives promise of brilliant and rapid developments in natural science in general and in chemistry in particular. In this belief I venture to lay before you some reflections upon the growing recognition of the importance of our science and upon the responsibilities with which, owing to this change in public opinion, our shoulders are laden.

I have often heard the statement made by men who have grown old in the service of science that chemistry, and particularly applied organic chemistry, is a subject in which the British nation can never excel; that minute attention to detail, coupled with the power of organization and coöperation, entails something antipathetic to the British character; the Germans, we know, have often expressed this view. The events of the last three years have sufficed to dissipate this fallacy forever. The manner in which Great Britain, caught in the autumn of 1914 with scarcely any resources in the shape of equipment for the manufacture of fine organic chemicals, has rapidly become a larger producer of explosives, pharmaceutical, photographic and other essential chemicals than Germany will remain an enigma to the historian of these present times. The obscurity which surrounds this rapidly executed operation is not diminished by the existence of difficulties which have naturally acted as inhibiting agents.

This country enjoys in a greater measure than other states a representative government, and, in spite of the many advantages of such a form of government, the fact remains that it necessarily admits of no representation of any phase of public opinion not loudly and insistently expressed. Science has always been in this latter position; it has been unvocative. During the first few years of the nineteenth century, Dalton enunciated the atomic theory, Thomas Young stated the undulatory theory of light and James Watt invented the steam engine, and by these events all the amenities of human life have been revolutionized; indeed, they have exercised vastly more influence on the well-being of our race than did the Napoleonic wars. So accustomed are we, however, to routine habits of thought that most of us would probably answer, in reply to a suddenly posed question,

that the battle of Trafalgar was the most pregnant event of the first quarter of the nineteenth century.

### THE POLITICAL POSITION OF CHEMISTRY

A brief moment of reflection would lead us to correct this hasty statement. Sodium was discovered by Davy in 1807, and benzene by Faraday in 1823. From sodium we obtain sodamide, the prime agent in making artificial indigo an economic possibility; the separation of benzene from coal-tar led by logical sequence to the production of Perkin's mauve and of thousands of other synthetic coloring matters, and to the manufacture from coal-tar anthracene of synthetic alizarin, the first heavy blow aimed at the position of the Turkish Empire, involving as it did the ruin of the Turkey-red or madder industry. The first practical process for making aluminium depended on the use of Davy's sodium, and with the aid of Davy's safety-lamp 250,000,000 tons of coal are mined annually in this country with comparatively slight risk. Faraday's early investigations on the chemical aspects of electrolysis and his studies on magnetic induction led immediately to the invention of the dynamo, and, through Clerk Maxwell, to the introduction of wireless telegraphy; this one branch of Faraday's investigations, in point of fact, constitutes the ground-work of the whole stupendous vista of results of the general introduction of the electric current into modern life which is so familiar to us all. Cavendish's early production of nitric acid by the passage of an electric spark through air, reproduced on an enormously larger scale, is now furnishing Central Europe with the nitric acid without which no explosives could be manufactured.

Any one who is in the habit of reading modern historical writers—and they have become quite illuminating since a scientific mode of writing history has been substituted for the older fictional style—knows how political changes, national reforms arising from an effort of the collective conscience, the magnetic influence of some popular demagogue, and the like, are invariably invoked as explanatory of all the vicissitudes of our planet.

The modern historian is here taking a false point of view, and since he is, in general, quite unacquainted with physical science, his methods are inadequate. The whole history of Europe for the last century has been made within a few hundred yards of Burlington House in our scientific laboratories. One of the most potent incentives to political changes resides in the desire to increase the amenities of life, and research in pure science has had for a hundred years past the greatest influence in facilitating the realization of that desire.

\*Abstract of the presidential address delivered at the Annual General Meeting of the Chemical Society, March 21, 1918, in London.

Coöperative effort, one of the most striking aspects of modern life, only became possible when science provided the facilities for municipal power schemes, for telegraphic connection over the whole world, and for the concentration of production in definite centers. Chemical science is still furnishing the means for further revolutionary changes; during the last few years we have seen great technical developments of purely scientific discoveries—the work of Dewar on the liquefaction of gases, and that of Cross and Bevan on viscose and artificial silk, both of which have led to the profitable utilization of vast amounts of capital—and it is as yet impossible to indicate the ameliorations of the conditions of human life which will inevitably result from contemporary chemical investigation.

In a time of crisis like the present, British custom tends toward the replacement of unreal conventions by what is really vital; we have been engaged upon this operation for several years. While previously unheard-of changes have succeeded each other kaleidoscopically in the national constitution, in the political parties in power, in the freedom of the subject and in hosts of other ways, the nation has recognized that science is the only real maker of history. The whole empire is now one vast chemical and engineering laboratory, and we even live on a scientific ration of so many calorific units. It is obvious that chemistry, with physics, engineering, preventive medicine and others of the natural sciences, which previously had no imperialistic position, because powerless to make or break a Government, have become the pivot on which turn all our hopes of retaining an independent national existence; it has been suddenly realized that supremacy in these branches of knowledge is vital to our country.

#### THE POSITION OF SCIENTISTS IN THE STATE

The time is approaching when this state of affairs will change; neglect of the natural sciences will then no longer put us in danger of sudden extinction, but, as was taking place years ago, will lead to our slow, certain downfall as a nation. The responsibility is placed upon our scientific men of taking such measures as will insure that the old order is not re-established, that science makes her voice heard in our national councils and that policies of drift are forever abandoned.

We have in this country three large and long-established organizations devoted to various phases of chemical science: the Chemical Society, the Society of Chemical Industry and the Institute of Chemistry. It is too much to ask that these three representative bodies, with perhaps the newly-founded Association of British Chemical Manufacturers and ultimately all the other cognate but more specialized interests, should set up a watchful and alert joint council with directions to consider national questions in which any of the varied interests of chemistry are concerned and to make such representations to our administrators as would voice the corporate view of the joint body.

I am inclined to think that, had such a body been in existence several years ago, much that has been accomplished in the interval by somewhat devious methods would have been better done. One instance will occur to every one: that of the much-debated question of the re-

establishment of the coal-tar color industry in Great Britain. The scheme adopted by the Government for resuscitating this phoenix in our country, after its past thirty years of profligate productivity on the Continent, was launched without scientific advice; the Cabinet mouthpiece, indeed, declared that the directorate of the company was not to include men of scientific knowledge, on the ground that a director who knew something about the business of the company would have an advantage over his less well-informed colleagues.

Owing largely to the fact that we possess no strong collective council, representing the combined academic, scientific and industrial aspects of our science and capable of representing them before a representative Government, it may be argued that we chemists are not altogether blameless for the particularly blundering way in which particular errors have been perpetuated by the responsible officials. While we should be thankful that our blunders have not led to our destruction, we should proceed without further delay so to organize the resources of chemistry as to make it possible to enforce the adoption of scientific methods and modes of thought by authorities to whom these are yet strange.

The serious character of the British position in connection with the coal-tar color industry becomes more evident when one considers that this is a key industry; upon it depend the textile, paper, photographic and pharmaceutical industries. The total capital employed in the organic dye industry in Great Britain is between four and five million pounds, while the capitalization of the German coal-tar color firms is of the order of fifty million pounds. The need for greater and more intelligent activity in this direction is obvious; unless national enterprise can be stimulated into providing adequately for the manifold requirements of Great Britain and her colonies in all those industries which depend on coal-tar color manufacture, we shall be again in the hands of the foreign producer.

The control of a national dye scheme by business men with no real feeling for the enterprise on which they are engaged renders it fairly certain that the wider aspects of coal-tar color manufacture will be neglected. The interweaving of the color interests with those of synthetic pharmaceutical, photographic and other chemical industries is essential to success. The utilization and development of the resources of the empire in natural coloring matters such as indigo is necessary from a national point of view. The careful study of our own and other codes of patent law in their bearings upon the fine chemical industry is also important. These weighty questions cannot receive adequate consideration from any purely lay body. It is mournful but instructive to compare our present position in the coal-tar industry with the prospects which that branch of applied chemistry exhibited to Great Britain in early days. The first coal-tar color was made by Perkin in 1856, and in 1862 Prof. A. W. von Hofmann, one of the foremost chemists of the day, a German, domiciled in this country, painted an alluring picture of the future in store for us. Said he: "England will, beyond question, at no distant day become herself the greatest color-producing country in the world, nay, by the strangest of revolutions, she may ere long send her coal-derived blues to indigo-growing India, her tar-distilled crimsons to coch-

ineal-producing Mexico, etc." When we contrast this dazzling prospect, made by one of the most far-sighted of contemporary German chemists, with the actual situation, we cannot but ask why the event fell so miserably behind the forecast.

### THE MODERN EDUCATION

The reason, in my opinion, lies in the fact that opulent, indolent Great Britain has for the past century permitted all its educational interests to pass into the hands of a particular caste which despises all knowledge difficult to attain, and, to camouflage its own idleness, has always pressed the notion that a first-hand knowledge of the facts of natural science and the conclusions to be drawn therefrom is unimportant, and that the young man or young woman does his or her best in the world if thrown into it entirely destitute of anything but an evanescent acquaintance with certain classics and a decided taste for so-called learned leisure. The greater among the ancients were creators of new knowledge as well as masters of the whole accumulated world's stock of information; their successors, unproductive of positive knowledge and very ignorant of the great changes taking place around them, can but wonder at and comment vaguely on the genius of Archimedes and Aristotle, and necessarily despise the achievements of Newton and Kelvin, their modern prototypes. Illustrations of the stultifying effect of a purely classical education are laid before us every day; one recent example may be quoted here. The gentleman who shares with Mr. A. J. Balfour the honor of representing in Parliament the greatest center of business and financial activity in the world made the following statement in the House of Commons recently while opposing Mr. Fisher's Education Bill: "It was said that education was necessary to make the rising generation good business men. His experience in the City was that the man who took Firsts at Oxford generally came out last, and that the man who could hardly write his name generally came out first. The explanation was that education could not put into a man that instinct of self-preservation and common sense which was the foundation of all success in business. How could education assist a farm laborer to spread manure on a field? The best laborer he had known was wholly illiterate. If the waste of the war was to be replaced, it would be necessary for the young to start as early as possible in doing a day's work, instead of wasting time on useless book learning." This representative of the City of London is a baronet of recent creation and a director of one of the largest London banks and one of the most important English railroads; he received his "education" at one of the oldest and most rigidly classical of our great public schools. Comment is probably unnecessary.

Every scientific man in the world realizes that an innate appreciation for fine literature, for great thoughts nobly expressed and for the appropriate delineation of our greatest aspirations are among the most sublime instincts of humanity and demand the most careful cultivation. Our literary men say that we cannot express ourselves effectively, and offer as a satisfying feast the old bones left us by the Greeks and Latins, chewed over for centuries until so devoid of nutriment that they led ultimately to the mental atrophy which characterized

the Middle Ages, an atrophy that was only shaken off by the taste for knowledge which arose from the exploits of geographical science in the Elizabethan period.

If the power of expression rests with our literary friends, why are they so idle? It is their obvious duty to devote themselves to popularizing the natural knowledge acquired by the scientific observers of the past two centuries; this real learning has so infinitely extended human interest in the world around us and gives such promise of further conquests that an appeal for its consideration would certainly not have been made in vain to Plato or Lucretius. No one asks for the abolition of classical literary learning, but the whole world is now demanding that the young should be provided with an education which includes an insight into our present-day knowledge of the universe.

The rather petty disputes which rage about this matter of classical and scientific education are one-sided; the scientific man generally knows something of both aspects of the subject, while his classical compeer rarely has any acquaintance with science. Unfortunately, the great questions involved have more than a petty bearing upon the well-being of our nation. The classical school has held our country in such bondage that, to all practical intent, no person can be admitted to the higher public service unless he swear adhesion to the caste. It is almost regarded as a platitude that acquaintance with natural science disables a man from fulfilling any high public office; practically all the superior positions in the Civil and Diplomatic Services must be filled by men of classical instincts.

### TRAINED MEN FOR GOVERNMENT STAFFS

I venture to think that the wisdom of this mode of selection has been seriously impugned during the last four years. The huge Government departments which have arisen of late may be divided roughly into two classes—those staffed by men of some scientific training and those staffed by classical university graduates. Any one who has had occasion to note the numerous recent criticisms on Government departments must have observed that these strictures have almost invariably been passed on administrative branches of the service: delay, the encumbrance of red-tape and inability to draw a decision seem indigenous in certain Government offices, and none of the numerous attempts at reform has been successful. The administrative services are those in which the classical man is predominant. Other branches, such as the home Army Medical Service, have practically never been charged with inefficiency; the worst that has been alleged is a suggestion of extravagance.

The department just named is staffed by men who have had at least the rudiments of a scientific education; if control in the Royal Army Medical Service had been vested in the classical scholar of ability but no knowledge, it is certain that the last three years would have seen a repetition of the Crimean campaign horrors and that the army mortality from disease would have been greater than that caused by the instruments of war.

Such a control, happily, has been avoided; it has been avoided merely because medicine possesses the collective organization for which I plead in chemistry, an organization so strong as to make the imposition of an irresponsible lay control unthinkable.

I have already directed attention to the frequently expressed opinion that, as a nation, we are incapable of excelling in the fine organic chemical industry; let me quote one instance, small in itself, but large in its consequences, in disproof of this view.

The ordinary photographic plate is sensitive only to a region in the blue of the spectrum, but by incorporating certain rather fugitive organic dyes with the sensitive film, the latter may be rendered sensitive to the green, yellow and red parts of the spectrum; photographic plates so treated are described as panchromatic. The quantities of the sensitizing dyes required for the whole world's consumption in normal times is minute, being, indeed, of the order of a few pounds per annum. Until 1915 these substances had never been made outside Central Europe, and little was known by us of their compositions or of the methods of preparing them, as they were all sold under trade names. The manufacture of these materials, small as was the whole business, had been industriously cultivated by the German color works, and, as these color sensitizers are essential in aerial photography, their scarcity became of serious import quite early in the war.

The experimental investigation of the whole subject was quickly put in hand in this country, and within a few months ample supplies of the usual sensitizers were produced. Further, the newly established Department of Scientific and Industrial Research financed the development of the study of photographic sensitizers; as a result of this action new sensitizing dyes have been produced which are far superior to the older ones. It is safe to assert that the manufacture of panchromatic plates has now attained a degree of perfection in this country such as will long defy competition.

This is but one case that may be quoted from among a host of others, all of which prove conclusively that, given a little encouragement and assistance, British chemistry is capable, not only of giving much needed relief in this time of strain, but of meeting every demand which can be made on it when the period of reconstruction commences.

While the absence of the powerful weapon provided by a collective chemical council, embracing all interests of the science, has made it impossible for us to render the most economical service to our country, it is perhaps satisfactory to reflect that hitherto all that has been sacrificed is economy. Our lack of power to enforce our views has led to financial extravagance on the part of the authorities; the lack of economy in time, which means lives, cannot be attributed to our chemists. The duty will fall to some future President at some later time to record the spontaneity with which the Fellows of this Society volunteered for service in our chemical works, our munition factories and with the Colors either in our gas service or elsewhere.

One aspect of this question, however, calls loudly for attention. For several years past our teaching staffs have been depleted, and but a small fraction of the normal number of young men have been able to present themselves for training in chemistry. While the present demand for capable young chemists is vastly in excess of the supply, an even more serious situation awaits us in the future. If hostilities were to cease tomorrow, five years would be needed before our colleges and universi-

ties could begin to supply the large numbers of young chemists which will be required for the development of the future great fine chemical industry of this country.

Surely this is a matter which should engage the serious attention of the country. If it prove necessary to import young chemists from neutral nations to man our reconstruction schemes, a handicap will be established which we may never outrun. The adoption of some scheme by which a sufficient number of juniors can be provided to help in the great developments which the future has in store for the scientific industries of the country is of the utmost importance.

#### THE VALUE OF CENTRALIZED ORGANIZATION

It is impossible to reflect on the desirability of a closer coöperation between the large societies representing chemistry in Great Britain without foreseeing many directions in which such a union would be of value. As in every time of awakening, there exists at present a great feeling of unrest among the younger members of our profession; of late quite a number of propositions for the formation of new scientific societies have been promulgated, and all for the purpose of placing more power in younger hands and for insuring to the juniors more security of advancement. The final objects of these propositions, so far as I have understood them, are entirely praiseworthy, but it is to be feared that the methods suggested for their attainment are not always such as appeal to older and more experienced people as likely to prove successful. If we chemists collectively were in possession of some more centralized organization, such a one, for example, as is represented by the Chemists' Club in New York, with facilities for hospitality, meetings, library, laboratory accommodation and the like, no question could ever arise of the creation of a new chemical body unconnected with the main organization. A new and vigorous issue of the parent organization would shoot at appropriate intervals, and would remain contributing to the strength of the family under the original patriarchal roof. We greatly need a central home of all the chemical interests in the country, and premises, several times as large as the Chemical Society rooms, to use as a club, of which every chemist in the country would be a member. The question of the necessary expansion of the library, which is occupying the earnest attention of your Council, would find an easy solution in such a pooling of interests.

Notwithstanding that during the past forty years much has been done to facilitate the entrance of talented and promising young men into the scientific professions, far more progress must be made in this direction if we are to regain for Great Britain the paramount position she once held in scientific discovery. The Natural Science Departments in every university in the country call for expansion in personnel, laboratory space and equipment, and in provision for post-graduate research work; while scholarships for students in training are fairly plentiful, the difficulties which face the advanced student who needs to spend and who would benefit immensely by spending several years on original research are often insurmountable. Every professor of chemistry in the country can recall many instances in which he has had to send his students into technical life at too early a period, simply because it

has been impossible to secure for a good man the £150 to £200 per annum necessary for living expenses; the provision of this small sum would, in many cases, convert a half-trained chemist into a far greater asset to the state.

While a collective effort, exerted by all the interested branches of our science, to insure the efficiency of the newly-established organizations for furnishing the requisite relief is urgently desirable, it should be noted that it will become increasingly difficult to retain students capable of taking leading positions for a sufficient time to insure their proper training. During several years past I have been visited by gentlemen representing large chemical industries who have walked around my research laboratories to sort out the workers and to make overtures to such as they judged suitable for their own work; the pressure thus exerted upon the universities to force the premature delivery to the work of the best men they have in training will necessarily increase with the coming still greater demand for technical chemists.

#### GREATER REMUNERATION NEEDED

The intellectual professions may be roughly classified in two categories: the productive and the parasitic. Those of the productive class, which include all scientific workers who produce new knowledge, are, in general, poorly remunerated; their practitioners are ordinarily so intensely held by the interest of the work in hand that they have little inclination to divert their energies to the necessary extraction of higher emoluments. The parasitic class, on the other hand, have always been able to command ample remuneration for their labors; the reasons for this difference are various, and need not now be detailed. It may be noted, however, that at the jubilee of this Society in 1891 the veteran, Sir W. R. Grove, who in his young days did so much to develop chemical science, told us that he was led very reluctantly to desert chemistry for the law because "the necessities of a then large family gradually forced me to follow a more lucrative pursuit." The autobiography of the late Lord Playfair tells a precisely similar tale. Neither of these men is now remembered by anything beyond the great achievements in chemical science of his early days.

The fact emerges that if science is to retain in its service such a proportion of the most powerful intellectual and creative talent of the empire as will suffice for our progress as a nation, some method must be devised for securing to its followers appropriate emoluments commensurate with those now allocated to the non-productive professions.

This is not only necessary in connection with those purely utilitarian branches of chemical science to which I have already directed attention, perhaps too insistently, for illustrative purposes. A great danger exists at present, and will grow in the future, that the enormous productiveness of experimental science will overshadow the importance of scientific work of less immediate utility. It would be a great calamity if pure science were neglected in favor of the cultivation only of natural knowledge which gave immediate promise of beneficial material results. One of the most important functions of any expression of collective chemical in-

terest such as I have foreshadowed would be to insure that pure unproductive scientific research should be retained on an even higher level than that assigned to immediately productive original investigation.

At the present time physics and chemistry are merging into one; we foresee that the near future will furnish us with still broader views of the universe and will mark a new development more illuminating even than the great advances which followed Dalton's atomic theory and all its nineteenth century sequences. No material interests must be allowed to check this stupendous expansion of our knowledge.

**Hardness of Ingot Iron and Copper:—**F. C. KELLEY in the October, 1918, issue of the *General Electric Review* studies the hardness of ingot iron with a view of producing metal capable of replacing commercial copper where the latter is used merely on account of its softness. The iron tested contained

**Behavior of Iron Compounds at Extremely High Temperatures:—**Following studies of the spectra of iron and its compounds in flames and furnaces, G. A. HEMSALECH (*Philosophical Magazine*, Vol. 36, p. 209) concludes that the iron atom is not permanently detached from its compounds by the action of heat. He used a resistance furnace consisting of a heat-insulated carbon tube 14 mm. internal diameter, 3 mm. thick and 6 in. long, clamped between heavy graphite terminals. The iron spectrum appeared in the furnace from 1500 deg. C. to 2400 deg. C. whether metallic iron was present or not, and corresponded to that given by any iron compound fed to the cooler of the following flames:

|                                | Deg. C. |
|--------------------------------|---------|
| Air-coal gas (cone), less than | 1700    |
| Air-coal gas (mantle)          | 1850    |
| Oxy-coal gas                   | 2450    |
| Oxy-hydrogen                   | 2550    |
| Oxy-acetylene                  | 2700    |

The spectrum is restricted at lower temperatures. At about 2500 deg. C., the boiling point of iron, a general change in the character of the spectrum occurs.

From the evidence the author concludes that the furnace- and flame-spectra up to about 2500 deg. C. are caused by the partial dissociation of compounds due to heat, and while the orbital motions of its components are changed, the compound retains its individuality throughout. On the other hand, in the explosion region of the air-coal gas flame the iron atom, thanks to its strong affinity for nitrogen, is free during the time necessary to change into a nitride, and the spectrum of this flame shows a high degree of development comparable to that observed in the arc and spark.

# Metallurgical Practice on Cinnabar at Idria, Austria\*

A Description of the Plant Installation and the Types of Furnaces in Use,  
Including Shaft, Cermak and Kroupa Furnaces—Condensation of  
Mercury—Soot Treatment—Production

BY DR. ROLAND STERNER-RAINER

**I**DRIAN quicksilver operations have withstood the vicissitudes of troubled times for over five centuries. The story of Idria's past has been related to us by conscientious historians, who have shown not only the influence of the world's affairs on its prosperity and development but also the development of its metallurgical practice.<sup>1</sup> In the following will be described not only the current practice but also the improvements which are planned for the near future based upon recent experiments.

The Idrian ore body is associated with the conglomerates and the typically Idrian "Skonzaschichten" (black, bituminous slates and sandstones interbedded in the Wengenschichten, carrying fossil plants) of the upper Triassic and with dolomite breccias, dolomites and the Guttensteiner limestones of the lower Triassic.<sup>2</sup>

The broken ore, which is hand-sorted in the mine into plus and minus 2 per cent material, is transported to the ore-dressing plant (Fig. 1.) in cars having a capacity of 700 kg.

## CRUSHING AND SIZING PLANT

The ore is dumped on a 90-mm. vibrating screen (Seltner patent). The plus 90-mm. material passes to a rock crusher, which discharges on another screen, the fines of which constitute the so-called "armer Erzgries" or low-grade fines. The coarse material is fed to a circular rotating sorting table, from which high-grade ore and material to be recrushed is picked out. This high-grade ore is hoisted and treated with the hand-picked ore coming from the mine. The minus 90-mm. material passes to another screen of 20-mm. mesh, the plus 20-mm. material going to a pickling belt, where ore, wood and waste are separated. The "armer Erzgröb," or low-grade coarse, drops into a bin. The minus 20-mm. material ("armer Erzgries," or low-grade fines) is partly screened through a 4-mm. sieve. The 4- to 20-mm. product and the 0- to 4-mm. product are called "armer Erzgries a and b," and are stored in ore

bins. The plus 2 per cent ore is crushed in a small crusher after the large pieces have been hand-cobbed to suitable size. The crushed product passes to a shaking screen equipped with a suction hood to avoid the dust problem. The material passing the screen is fed to crushing rolls, from where the ore passes to a revolving screen of 4-mm. mesh, which completes the classification. The over-size is returned to coarse crushing rolls with a bucket elevator and is screened into two products, which are fed to medium and fine crushing rolls. Both of these rolls feed a revolving screen of 4-mm. mesh, which again gives a coarse and fine product. This extensive crushing of the high-grade ore is believed to insure complete roasting in the furnaces and the consequent avoidance of large mercury losses. The richer the ores are, however, the less crushing is necessary, as the escape of the subliming cinnabar leaves a porous rock, the porosity being greater the richer the ore, so that there is no possibility of the rock entirely enclosing the cinnabar.

The dressing then gives the following product:

|                                        | Mercury<br>Per Cent | Mesh<br>Mm. |
|----------------------------------------|---------------------|-------------|
| a. Low-grade:                          |                     |             |
| 1. Low-grade coarse                    | 0.340               | 20 to 90    |
| 2. Low-grade fines                     | 0.463               | 0 to 20     |
| 3. Low-grade fines a                   | 0.440               | 4 to 20     |
| 1. Low-grade fines b                   | 0.815               | 4 minus     |
| b. Ores containing over 2 per cent Hg: |                     |             |
| 1. Fines                               |                     | 4 to 20     |
| 2. Dust                                |                     | 4 minus     |
| c. Ores containing over 5 per cent Hg: |                     | 4 minus     |

The ores, which are hauled to the plant by an electric locomotive, are carefully weighed and sampled. Ten grams is taken for an assay sample with low-grade ore, two grams for high-grade ore and 0.5 gram of the very rich material. Kroupa's modification of Eschka's gold cover assay method is used. The moisture is estimated at 2 per cent.

## OPERATION OF SHAFT FURNACES

The low-grade ores are burned in eleven shaft furnaces (Fig. 2), two of which have a circular cross-section and are slightly smaller than the others; the capacities are 15 tons in 24 hours for the larger and 13 tons for the two smaller ones. Some of these furnaces are equipped with Spirek's<sup>3</sup> automatic charging device, the others are closed with bell-like charge covers, through which the furnaces are charged every two and a half hours. The operation of the charging device is as follows: The iron hopper is filled with about 600 kg. ore from the charge car, and a load of charcoal ( $\frac{1}{2}$  cubic meter) or coal (60 kg.) is spread over it. The second charge car is held in reserve and

is dumped when the hopper begins to empty, which occurs when the water-sealed charge door cover is opened; the bottom of the hopper on which the charge rests now swings down on a frame which has moved across the charge opening. On closing, the charge hopper cover is replaced, the frame moves back, making room for the charge door cover; at the same time the hopper bottom is raised and the hopper can be refilled. This device works quickly and allows almost no escape of

This process is far too tedious to suit the workman. The gases above the cone were formerly drawn into a special condenser system, but the only result of this attempt was that the lowered pressure caused a greater flow of gas into the space between the cone and the charge-cover, and for this reason the device has been abandoned as impractical.

The tailings are drawn as fresh ore is charged, cooled with water and returned to the mine for fill. At the first removal of tailings during the morning shift, 10 kg. are taken as a sample, which are tested twice a month. The sample is reduced and about 10 or 20 grams are taken for assay. The tailings content varies between 0.0005 per cent and 0.0025 per cent. The crew is five chargemen and five drawmen. The shaft furnaces treat 42 per cent of the ore and their extraction equals 92.37 per cent of the contained mercury (loss 7.63 per cent).

#### OPERATION OF CERMAK FURNACES

The low-grade fines are treated in three old Cermak-Spirek fine-ore furnaces and one new and modified furnace of this type, which is fired with producer gas. The first Cermak fine-ore furnace erected in Idria was equipped with a "generator" at the ends of the furnace.

These generators, which, in construction as well as in operation, resembled "semi-gas producers," were not a success and were later replaced by grate fires, which system is still prevalent in the plant. Because of the importance of gas fuel to quicksilver metallurgy, a new solution of this problem was undertaken at the instigation of H. O. Kroupa, despite the former failure. The encouraging results will be discussed later on. Each of these older furnaces is really a combination of four 10-ton furnaces which have been joined in order to achieve a more efficient use of heat. Every 2½ hours, or three times per 8-hour shift, the tailings are drawn into an iron car. These are sampled with a long-handled scoop; the sample is reduced, mixed with

FIG. 2. VERTICAL SECTION OF NOVAK SHAFT FURNACE

FIG. 1. CRUSHING AND SIZING PLANT AT IDRIA

charge gases and has proven very satisfactory, except that the trough of the water-lock can become clogged with ore or coal and so prevent complete sealing. The covers tend to warp with excessive temperatures and then close the opening imperfectly. A hole is left in the furnace top near the charge door, through which the height of the ore column can be measured with a wooden rod. This hole is stoppered with an oakum-bound iron plug. Generally, a single charge of two or three cars fills the furnace.

At the shaft furnaces, closed with a cone and cover device, the necessary number of charge cars is spotted, each second car being filled with the measured 2½ per cent of fuel. Here also wood and coal fuel are alternated from shift to shift in order to maintain a constant heat. Attempts to replace wood or coal by coke have not favored the latter practice. When the preparations are completed the counter-balanced cover is quickly raised by means of two levers; the cone is raised as soon as the ore has been dumped and the cover is quickly replaced. This operation is repeated until the furnace is filled. If the shaft becomes full, so that the ore no longer flows into it, the cone is replaced as well as it can be, and the circular hopper cover is set into its water seal. During this manipulation, which is quickly completed, some noxious gases escape from the furnace and the correct way of charging with this device would be not to lower the cone until the cover has been replaced and to repeat this process with each car of ore charged to the furnace.

hammerscale and heated for ten minutes (measured with an hour glass) over an alcohol flame. A completely burned charge should not give the faintest mirror of quicksilver on the enameled water-cooled cover of the

crucible. If no mirror is deposited, the tailings, which at most can contain 0.005 per cent Hg., are drawn into cars and hauled by a 10-hp. gasoline locomotive to a rock bin which is situated over a sluice leading to the Idriza River. After drawing, a corresponding amount of ore can be charged. The capacity of Nos. 1 to 3 furnaces, which are fired with beech or fir wood or with brown coal, is 45 tons of ore. Since one furnace block (that is, four shafts) has eight draw doors, eight cars at 0.5 tons each being drawn every  $2\frac{1}{2}$  hours, the same amount being charged, the ore remains in the furnace full 32 hours. The charged material is evenly spread about over the topmost furnace tiles with rakes. Since as in Italian practice the

FIG. 3. CROSS SECTION SHOWING TILES IN CERMAK FURNACE

upper row of tiles is not connected with the furnace flue, and since the charge gases rising between the upper tile the roofs pass out through their own condenser system, the charge floor remains free of gas because the greater draft draws off the gases from beneath the upper gable. This also serves to remove the moisture which would otherwise condense on the charged ore. Even when the upper row of tiles becomes uncovered there is little evidence of escaping gas. As noted, these furnaces treat about 45 tons of low-grade fines per 24

it is unnecessary to screen the low-grade fine ore, as it will even treat the dust successfully. The space between tiles (see Fig. 3) was fixed at 80 mm. instead of at 100 mm., as is customary in the old furnaces. Since gas fuel is used, the roasting zone in this furnace is increased, thus increasing the capacity. The furnace has ten rows of superposed gables with the same over-all height of the old six-gable fine-ore furnaces; for this reason the gables were made slightly flatter. Each of the four furnace shafts is divided into three parts by two walls, so that each gable, likewise divided into three tiles, can be more easily and cheaply be replaced if damaged. The two upper gables, which are made of cast iron, are kept under a greater draft than the other parts of the furnace. The two lower gables, which serve to preheat the air, are not heated except by descending hot ore. The flame may be regulated according to requirement and the feed of the producer gas may be regulated by suitably placed dampers.

The gas producer was originally designed for coal and wood, but was soon changed to an all-wood feed because of excess clinking. Supt. Slavik has successfully managed not only to dispose of the enormous development of wood tar by an improved condensation system, but has also devised a system by which one cord of wood can be charged into the generator at a time. The furnace results with producer-gas firing are satisfactory in every respect. The capacity of the furnace is now 85 tons per 24 hours, nearly 100 per cent greater than that of the grate-fired furnaces. The wood consumption per ton of ore treated (0.14 cubic meters) is no greater than before. Above all, the gas fuel not only causes a richer soot to form in the condensers (the soot being only slightly contaminated with tar and dust) but about half of this mercury is recovered as free metal. Less soot forms than formerly, which is beneficial not only from an economic but also from a hygienic viewpoint. For these reasons it is proposed to construct another of these furnaces of doubled capacity.

By the use of producer gas the temperature in any of the 12 gable rows can be raised to any desired de-

Longitudinal Section

Cross Section

FIG. 4. WOOD-FIRED REVERBERATORY FURNACES

hours, while broken tile in the furnace reduces the capacity to 40 tons. Such furnaces are charged with dustless fines, which it treats more advantageously and quickly.

In order to relieve the reverberatory furnaces treating minus 4-mm. ore, a gas-fired fine-ore furnace of 80-ton capacity was built a year ago. With this furnace

gree, as each of the gable rows can be heated individually. The flow of gas and air can be so regulated by means of dampers that a constant difference between the temperature of the roasting gases and the temperature of the ore can be maintained. According to Dennis<sup>1</sup> an even fall of potential of this kind increases

<sup>1</sup>Engineering and Mining Journal, 1909, No. 3.

the speed of the heat transfer in the furnace, so that a saving of time and fuel should result. Since the flow of air and gas can be completely controlled, the draft can be increased so that suction can be maintained even in the lowest row of gables, causing air to be drawn into the peepholes rather than letting gas escape from them. Not only can this regulation determine the speed of the gases through the condenser system, but the air around the furnace will be purer and healthier for the workmen.

The new furnace, which will be one meter higher than the others and have an automatic draw and the usual iron sheathing, will also be employed in furnacing

material have been developed. Last year 8 per cent of the tonnage was treated in these furnaces with a loss of 10.14 per cent of the input. Since low-grade dust, low-grade soot and pressed soot, however, will be treated in these furnaces for some time to come, they shall be briefly described. Fig. 4 shows these wood-fired reverberatory furnaces. The fuel consumption is 3 cubic meters of beech wood in 24 hours; this quantity is considerably less with very rich ore (over 50 per cent) as the combustion of the sulphur gives considerable heat independently of the heat from the fuel. The furnace will treat 7 tons of low-grade fines per 24 hours, but only half this tonnage of high-grade fines or soot:

FIG. 5. KROUPA'S FURNACES FOR INDIRECT REGENERATIVE GAS FIRING

low-grade fine ore.<sup>6</sup> In the future, a system of conveyor belts will feed all furnaces.

The fine-ore furnaces, which treat about half the tonnage, give an extraction of about 88.39 per cent of the input, while the small fine-ore furnace, which treats the high-grade fines (6.63 per cent Hg), works with a loss of 8.34 per cent.

The six bottom-fired reverberatory furnaces are to be discarded, since better methods for treating the fine

thus 4.3 per cent of wood is needed for low-grade material and twice this amount with rich material. The charge is moved every half hour with a long iron rake, and after three hours (longer with rich material) it is moved to a space in front of the fire arch which has been cleared by the removal of the former charge. One charge car of low-grade or a half car of high-grade material is now charged through a cone and cover charging device. A quarter of an hour before drawing the tailings a sample is taken from the center of the hearth by inserting a suitable shovel which is introduced in-

<sup>6</sup>The furnace is already in operation. The results are as predicted, the capacity being 119 tons, and this may be increased later.—EDITOR.

verted and then turned over. This sample is tested as already described; if no mercury mirror is shown, the tailings are drawn into iron cars and transported hot to the dump, where an automatic device discharges them into a sluice. The burned soot is used over again to press fresh soot.

#### KROUPA'S SHAFT FURNACE

Encouraged by the favorable results achieved by producer gas fuel, the Idrian plant will make an attempt to treat the coarse ore by a method superior to that of burning in the shaft furnaces. In the coming year Kroupa's patented shaft furnace will be erected, which it is hoped will be a further step toward the perfecting of quicksilver metallurgy (Austrian Patent No. 62,517). The fundamental idea of this furnace construction is to sublime the cinnabar between highly heated walls, then burning it by allowing a sufficient amount of oxygen to enter, and finally condensing the free mercury. The column of coarse ore in the shaft is relatively narrow and allows a free passage of gas. The heat, which is derived from the combustion of producer gas, is utilized as efficiently as possible, and losses by radiation are avoided by reducing the radiating surface. This also lessens the diffusion of mercury vapor into the walls. The separation of the gases of combustion and the mercury fumes must result, first, in an almost complete condensation of the mercury, and, second, in a minimum formation of soot (or dust and bitumen). At the same time the saving of space will result in less labor being needed, and the greater tonnage handled will result in lower maintenance charges.

In the execution of these fundamental ideas the furnace was given the general shape of a cube having a length, width and height of about 9.3 meters, the regenerators being built along two sides (see Fig. 5). In this cube are eight vertical parallel shafts separated by walls built of refractory masonry and containing the heating flues. The shafts are 0.5 m. wide and 7.35 m. long and, including the charge shaft common to two roasting shafts, are 6 m. deep. The roasting zone formed by the heating flues has a height of 1.5 m. Each shaft is divided into two symmetrical parts by a transverse wall 370 mm. thick, located at its center. The ore is charged through a gas lock into the common shaft; on descending is divided into two streams by a gable-like edge and descends through the roasting zone in two columns, each 500 mm. thick.

The oxygen necessary for the combustion of the cinnabar vapor enters through an automatically controlled opening connected with the operation of the automatic draw machinery and is gradually heated to the temperature of the roasting zone. On leaving the roasting zone the gases preheat the descending ore in the charging shaft, so that the gases are fairly cool when entering the condenser.

The walls of the roasting shafts are heated by leading producer gas into the heating flues, where it mixes with the preheated air from the regenerator and burns. The discharged heating gases are led into the opposite regenerator, and when this is sufficiently heated the flow of both air and gas is reversed. This effects an even heating of both sides of the shaft and an even roasting of the charge. Judging from experiments at the Zink-

hütte Cilli and experience with gas-fired fine-ore furnaces, this furnace should have a greater capacity than that of the present shaft furnaces combined, and the method of treatment is very much simpler.

#### CONDENSATION OF MERCURY

The metal-bearing gases pass from the furnace to the condensers through cast-iron pipes. The Cermak condensers (Fig. 6), consisting of straight and curved stoneware pipes, or more recently of glazed tile, following a suggestion of H. Auhagen, have a short leg extending from the bottom of the U into a water-filled soot box. The inverted U is closed by a stoneware cover lying in an annular water-filled trough. A shaft or a reverberatory furnace has four lines of condensers, a fine-ore furnace eight or nine (the new one is to have fourteen). They are sprayed with water as evenly as

FIG. 6. THE CERMAK CONDENSERS

possible in order to cool the furnace gases. To keep the cooling water out of the soot boxes the condenser pipes stand in a large cup, only the short lower leg extending into the soot box. The extra condensers for drawing off the water vapor from the upper part of the fine-ore furnaces are similarly arranged. This line of condensers, fed by a separate exit pipe, consists of only two vertical pipes, which accounts for the greater draft. The exit pipes from the furnace must be made of iron, as they must resist a high temperature and great temperature variations. They are very resistant and may last twenty years. With even cooling and the avoidance of careless handling, stoneware (or still better, glazed tile) is the most resistant of materials. Cracks are filled with cement and the two parts are bound together with iron hoops, since leaks must be stopped immediately to avoid large mercury losses. The cooled gases leave the stoneware pipes, in which they deposit the greater amounts of mercury, soot, tar, ore dust and water, and pass into chambers (often common to several furnaces) divided into several parts by transverse walls. These transverse walls by forcing a change in direction of the gas stream effect a more complete settling of the dust.

The chambers and flues are made of tarred wood throughout, as this most easily resists the action of the gases. The individual boards forming the walls are held in place with wooden screws and are luted with tar. Since a considerable amount of rich soot gather-

in the first chamber, this is hopped into a soot box, so that the chamber can easily be cleaned. Each of the chambers can be cut out by means of dampers. A 16-hp. exhaustor having copper vanes and a capacity of 7 cubic meters of gas per second is built into the flue and gives a draft of 80 mm. of water.

It is also proposed to abandon the central subterranean condensation chamber, as it is not easy of access and the detection and repairing of leaks correspondingly difficult. The purpose of this chamber was to collect the damp, poor grades of soot called "arme Kammerstupp." The 14-m. stack which stands 146 m. above the general plant level will be removed and replaced with a 30-m. stack with a Wislicenius top. It still remains to be seen whether the Cottrell precipitator will be effective in condensing the residual bits of soot and mercury. The method is excellent for collecting dust, wet dust and liquid globules, though in the latter application it is difficult to insulate the electrodes. These difficulties might even be greater in collecting soot, but are probably not unsurmountable. Without doubt the improvements in quicksilver metallurgy must be sought for in the process of condensation, as the perfection of furnace construction has improved the roasting process enormously.

#### SOOT TREATMENT

The shaft furnaces which treat only low-grade but nearly dustless ores give a little very rich soot, which is cleaned up every two months. The soot derived from the low-grade fines and the low-grade fines a is cleaned up each month; the soot derived from the high-grade fines and from burning rich dust and pressed soot in

the soot boxes additional mercury can be drained off. No fuel is added and no ore is charged during the clean-up, to prevent mercury fumes from escaping and injuring the workmen. The condenser line to be cleaned is cut out of the furnace draft with dampers, the gases meanwhile passing through the other lines. The cement luting of the covers and cleanout holes of the pipes are cut away with sharp irons, the covers are removed and the soot swept into the boxes beneath with long-handled, double-faced brushes. The water in the soot boxes is siphoned off on the side away from the furnace and flows through gutters in the concrete floor to settling boxes and sumps, where any mercury in suspension may settle before the water flows to waste. The soot boxes are emptied, starting from the furnace side, the soot being dipped into buckets standing on a sheet-metal saucer to prevent spatter losses, long-handled dip-pers called "Gatzen" being used. As the soot becomes

FIG. 8. NEW SOOT PRESS

FIG. 7. OLD SOOT PRESS

the reverberatory furnaces is cleaned up every fourteen days. The condensers of the reverberatory furnaces burning low-grade fines and furnace debris are cleaned up each month. Clean-ups are not needed oftener than every two weeks, even if 50 per cent ore is burned in these furnaces, as this does not form any additional soot and the mercury can be drawn from the traps into cast-iron pots without removing the soot. The collected mercury is dried with wood ashes and poured into storage flasks. This is also done before the clean-up at such other furnaces as yield a sufficient amount of free mercury. Since the mercury is mixed with the soot, it is necessary to agitate the latter in order to free the mercury. After the soot has been taken out of

very liquid after a part of it has been removed, burned pressed soot is added to thicken it, and finally the box is cleaned with these dry soot rejects.

Small amounts of metallic mercury are found in the soot boxes of even those furnaces treating very low-grade ore. If of considerable quantity it is poured into storage bottles; if not, it is dipped into the bucket with the soot. The filled buckets are taken to the soot mill in lots of six on a small iron flat car. A so-called "main clean-up" is held once annually, generally in July, during which the plant operation is entirely suspended, the furnaces repaired and the entire condenser system cleaned, including even the stack flue.

After the main clean-up the pipe soot and the rich chamber soot are put into boxes of about one cubic meter capacity, where they are allowed to settle. After a few days the clear water is siphoned off and the soot put into buckets and taken to the soot presses. Some metallic mercury always settles out on the bottoms of these boxes, and this mercury is poured into storage bottles holding about 60 kg. each; these are carried to the scales. An iron ring is placed in the box to facilitate the removal of metal; the soot in the ring is skimmed off, when the clean mercury, which enters between the ring and the bottom of the box, is dipped out.

One bucket of poor soot containing about 10 liters is generally sufficient for one soot-press charge (Figs. 7 and 8). With rich soot, which, however, is mainly metallic mercury, several buckets may be charged at once. When the press has been cleaned of the previous charge, a scoopful of lime is spread in it, the charge of

soot is added and covered with about three shovels of lime or burned soot rejects, and the machine is started. When the material has been well stirred additional lime is added until the mass becomes consistent; the time will depend on the moisture content and softness, but generally this stage is reached in half an hour. Most of the mercury is separated in about five minutes. To protect the workmen from mercury fumes, quicklime dust and the soot odor, the soot press is completely closed with a hinged cover containing a little charge hopper for the lime. The drain slots, on becoming clogged with soot, are cleaned by means of a mechanism which is actuated by a foot lever. Additional quicksilver flows out of the soot after each addition of lime, at first every two or three minutes, and later every four to six minutes. It gathers in the lowest part of the press and escapes through slots into a dish beneath, from which it runs to cast-iron pots, and is poured from time to time into storage bottles, which are taken to the weighing room. After pressing for about one hour (the pressing is really a mixing and continual cutting of the consistent mass), additional lime is added. The material then consolidates into lumps up to hazelnut size and yields no further mercury, which ends the pressing process. The soot press is now cleaned with a small, flat, chisel-like shovel, the walls and knives being scraped clean. The scrapings are removed with a scoop used to feed the lime. The pressed soot, consisting of dark to light gray nodules, is weighed and transported to the reverberatory furnaces to be furnace as rich ore, as it contains from 20 to 30 per cent mercury. Medium moist soot needs about thirty parts of lime to one hundred parts of soot. The soot presses are operated for one eight-hour shift per day. One press treats six or seven charges, although it could handle more; one operator per press is needed.

It has been tried to remove mercury from soot by centrifuging, but these experiments showed that in this process the soot consolidates into a hard mass without yielding its mercury. If, however, this treatment is preceded by a treatment with hot hydrochloric acid or by an extraction with carbon bisulphide, chloroform or ethyl acetate, the greater part of the metal will run together by centrifuging. The fundamental principle in the treatment with acid is the same as that employed in the soot presses. Instead of the saponification by means of the lime, which cleans the metallic particles of mercury from the adhering distillation and combustion products, we have in this treatment an acid saponification, while fats and oils are removed with the ether wash. This cleansing process allows the minute, disseminated particles of mercury to unite.

#### SHIPMENT AND PRODUCTION

Quicksilver is shipped in wrought-iron flasks holding 34.5 kg. Flasks destined for the Transvaal contain only 34 kg.; these flasks are designated with a red "T" and by being marked with red instead of white paint. The metallic mercury coming from condensers, soot boxes and soot presses is poured from oakum-stoppered storage bottles into an elevated iron pot. A drain pipe leads from the pot to a cylindrical clay weighing bucket with a conical bottom ending in an iron stop-cock, to which a hose is attached. When the beam balance points to zero the stop-cock is closed, the mercury is ac-

curately tared, and this mercury is run into the iron shipping flasks, which are then closed with a greased iron stopper. The flask is held in a vise while the stopper is screwed in. To test the shipping flasks for leaks they are inverted in an iron pan. If no leaks are found, it is ready for shipment. Some customers desire to receive their mercury in leather bags. For these it is filled in oiled sheepskin bags holding 25.08 kg. (55 lb.), two of these bags being shipped together in a small wooden keg.

The plant, which during the past year treated 117,110 tons of material, produced from these 762.5 metric tons (22,400 flasks) of metallic mercury.<sup>a</sup> Upon completion of the proposed improvements and plant additions, the production will probably increase considerably.

## Who and What Is the Employment Manager?

By C. T. CLAYTON

Director, Training and Dilution Service, United States Department of Labor

AS A MODERN business organization increases in complexity, further division of responsibility and more closely defined delegation of authority must be extended or the management will become chaotic. It is being recognized more and more that one most important function in a well-organized industrial establishment is the hitherto neglected responsibility of selection, placing and advancement of workers. This is what we mean by the term "employment management."

Employment management goes further, however, than merely concerning itself with such selection, placement and promotion. It investigates, as part of the selection, the character, experience and capacity of the applicant. It investigates for placement, and does not limit its investigation to the applicant. It sounds possibilities of openings for placement and it employs every means to secure the comfort and safety of the worker and thus assists his advancement by giving him a quiet mind and an assured future.

The employment manager is really the conscience of modern industry in practical action. In the old days, when employers had but few workers and themselves worked side by side with them, every worker was individually known to his boss, his idiosyncrasies were understood, his ambitions were appreciated because they were similar to the boss's ambitions. But now, when workers, numbered by the thousands, are employed by a collective boss who is a mere list of stockholders, living perhaps thousands of miles from the works and knowing the workers only as items of profit or loss on a ledger, some substitute for the old personal touch must be found or industry will become, first, congeries or unrelated items in reports, and, finally, mere anarchy. If modern industry is to be well-knit, is to understand and accomplish its real purposes, it must cultivate its conscience—the employment manager.

The usual method of business organization unfortunately has so far failed to take in this function as a distinct part of factory control. The foreman should not be charged with responsibility of selection of his gang. Good management does not require that he do so. Fac-

<sup>a</sup>Recovery, 6.5 kg. (14.3 lb.) per metric ton ore.

tory after factory has demonstrated that if the foreman's power includes that of sending back an unsatisfactory worker to the employment manager for removal and replacement, that is sufficient for purposes of discipline. But when it is considered that the cost of securing and training each worker ranges from \$10 to \$200, and averages probably more than \$60 each, a stupendous leak in the business which still clings to the antiquated foremanship hiring-and-firing methods is disclosed. Moreover, competent employment management reduces industrial misunderstanding and friction quite noticeably. In these days, when every nerve must be strained to obtain the highest possible output, no wise factory manager will ignore such a means of keeping the industrial peace.

Employment management differs from the public employment service. Some employers have been limiting their employment management to the status of mere labor recruiting agencies. That work should be left to the United States Employment Service; whose function is to find the labor and sift it in a preliminary way, offering those workers who seem likely to suit to the employment manager for his more intimate knowledge of the factory's needs, his more thorough methods of selection. The employment manager cannot be dispensed with in favor of the public employment agency any more than the public employment agency in this day of national need can be evaded. At least twelve millions of our working people are today engaged in the production and distribution of war supplies behind our military forces. Six millions or more will be required to fill the toll of increased demand brought about by the call of two millions to the colors before next July. Every available new source of labor must be tapped and carefully selected and trained before placing in industry.

### War Emergency Courses in Employment Management

An intensive training in employment management for men and women having a basic experience of at least three years' industrial experience and knowledge of factory methods has been arranged for in the following cities:

Boston—Harvard University, Massachusetts Institute of Technology, Boston University, New York—Bureau of Municipal Research. Rochester—University of Rochester. Pittsburgh—Carnegie Institute, University of Pittsburgh. Seattle, Wash.—University of Washington. Berkeley, Cal.—University of California. Courses are in preparation in Cincinnati at the University of Cincinnati, and in Chicago at the University of Chicago.

The courses, which run from six weeks to two months, are conducted by the Employment Management Division of the War Industries Board under the auspices of the Department of Labor, the War Department, the Navy Department, the United States Shipping Board and the Chamber of Commerce of the United States. There is no tuition fee. Employers having candidates for the courses and individual applicants desiring information should address Capt. Boyd Fisher, Employment Management Division, War Industries Board, 717 Thirteenth Street, N. W., Washington, D. C.

### New Jersey Chemical Society

At a meeting of chemists held at the Newark Technical School Monday evening, Oct. 28, action was taken in the matter of forming a permanent organization to promote the welfare of chemical industries and encourage the collegiate education of chemists in the State of New Jersey. The meeting was attended by more than fifty representative chemists of the state and assurance of cooperation and interest was given by forty-five others who were unable to attend. The title chosen for the organization was the New Jersey Chemical Society.

The first regular meeting for election of officers was held in the large auditorium of the Newark Technical School on Monday evening, Nov. 11. Applications for membership may be filed at future meetings. A constitution was adopted, and provision has been made for two classes of membership—firm members and individual members. It was the unanimous opinion of the meeting that this would insure for industrial chemists, for industrial corporations and for educational institutions in the state that close cooperation which will be so necessary in the development of the industries after the war.

The objects of the new organization as set forth are.

1. To provide opportunity for the periodic interchange of ideas relating to industrial chemistry.
2. To support, encourage and promote the general welfare of those industries of New Jersey which use chemicals and chemical processes.
3. To provide state commissions and municipal officials with competent guidance in problems of stream pollution, sewage disposal, water supply, fire prevention, pure food and health control, garbage disposal and street paving materials.
4. To provide a source for technical data relating to public utilities in order to promote the welfare of the State of New Jersey.
5. To further chemical education and provide standards of training for chemists in New Jersey.
6. To insure the permanency of chemical industries in the state by encouraging thorough collegiate training of chemists and providing a means of communication between chemical-industrial plants and our educational institutions.
7. To provide a means whereby banking institutions, investors, boards of trade and other commercial bodies may secure competent chemical advice.

The committee on organization consists of: Dr. Daniel R. Hodgdon, Newark Technical School; Dr. F. J. Pond Stevens Institute, Hoboken; Prof. Ralph G. Wright, Rutgers College, New Brunswick; H. B. Baldwin, chemist to the Board of Health, Newark; Carleton Ellis, consulting chemist, Montclair; Frederic Dannerth, consulting chemist, Newark; W. A. Lucas, the Butterworth-Judson Corporation, Newark; John Cawley, the Beckton Plant, du Pont Co. Newark; W. C. Stobaueus, the Charles Cooper Company, Newark; G. A. Prochazka, manufacturing chemist, Newark; James M. Reilly, the Board of Trade, Newark; Spencer Marsh, the National Newark & Essex Banking Co.; George T. Cottle, A. A. Wire Co., Inc., rubber covered wire; G. A. Armstrong, Central Dyestuff & Chemical Co.; W. E. Hadley, Clark Thread Mills, textile manufacturers; D. K. Howard, department of chemistry Newark Technical School; C. K. Simon, Dye Products & Chemical Co.; R. P. Calvert, du Pont de Nemours Co., Arlington; William A. Richey, National Carbon Co., Jersey City; S. Skowronski, Raritan Copper Works, Perth Amboy; C. L. Foster, Stubner Chemical Works, Elizabeth.

# Aluminium and Its Light Alloys—VI. Bibliography (a)

By PAUL D. MERICA

The following Bureau bibliography on aluminium and its light alloys is the supplement to the very comprehensive one assembled by the library of the United Engineering Societies and presented to the Bureau by Professor Zay Jeffries.

The numbers are references from the previous articles on the technology of aluminium in our issues of Aug. 1; light aluminium alloys, Aug. 15; miscellaneous alloys, Sept. 15; and Duralumin, Oct. 1.

(To Be Continued)

## A Practical Oil Circulating System For Indirect Heating

THE rapid advance of the chemical and allied industries during the last decade has created a demand for equipment that was radical in design and which in many instances the market was unable to supply, as the new products and methods of manufacture required apparatus that up to that time had not been produced.

This condition was especially true in regard to the method of supplying heat to the new equipment. The chemists had performed their part, when they determined what ingredients should be used and how to prepare the final compound. It was now up to the engineer to furnish the means of producing it on a large scale.

Many products required high temperature in manufacture with perfect and instantaneous control and uniform heat distribution. Uniformity of treatment of the product was necessary. High pressures were not desirable because apparatus of complicated design and generally with its inner surfaces enamelled could not be economically built to withstand high pressures. Elimination of fire hazards was sought because the materials were organic and often of an inflammable nature. These severe demands had to be met with a heating system that must be thoroughly practical, clean, free from interruption and easily operated by unskilled attendants. Points of no less importance to be considered were low costs of apparatus, insurance rates, repairs and upkeep.

The only available methods of heating were by direct-fire, steam or electricity. Direct-fire could not meet these requirements because of the difficulties in con-

high pressures, heavy and expensive equipment, frequent packing blow-outs and repairs, sudden changes in temperature and its inefficient temperature gradient made superheated steam undesirable, even in the few cases where it could be used. The only other method commercially available was electric resistance heating, but this was not acceptable. The apparatus in most cases could not be readily adapted to this form of heating. First cost of apparatus was high, the fire hazard great and the operating cost exorbitant.

With these rigid specifications in view, engineers naturally turned their attention to something new and decided to try out a high temperature circulating liquid system of which the domestic hot water furnace is a prototype. The problem then resolved itself into finding a suitable liquid material for conveying the heat, one that could be safely heated up to high temperature without chemical change and be free from carbonization and, second, into designing a heater and apparatus for circulating the hot liquid between chemical apparatus and the heater.

A number of attempts were made to build oil circulating systems, but when they were put into operation they were not successful because the type of oil on the market was not suitable for this class of service inasmuch as it coked and clogged the system. It was soon learned that the heat could be designed only after careful study and semi-commercial experimenting. Other difficulties with pumps and leaky pipe lines soon made it appear as though this method could not be practically worked.

The engineers of the G. M. Parks Company of Fitchburg, Mass., anticipating a number of years ago the urgent and surely increasing demand for an oil circulating heating system that would meet the most exacting requirements of the manufacturer, have devoted their entire time to the solution of the many problems that arose in connection with the installation and operation of such a system. The system they have evolved comprises the following elements: The absorber or heater, the circulating equipment, special pipe fittings and the heat conducting oil. These elements are usually connected with any type of apparatus to which the heat to be furnished by them is to be delivered by circulation. The circulating oil is mechanically circulated and passes through a specially constructed heat absorber. Then it is pumped through pipes to the apparatus to be heated—jacketed kettles, stills, tanks, etc. After delivering a certain controlled portion of its heat, the circulating oil returns through the pump to the absorber for re-heating. The entire system is under hydrostatic pressure from an expansion tank open to the atmosphere. The only additional pressure, rarely exceeding 15 pounds, is due to the frictional resistance of the pumped liquid.

The absorber and fuel supply may be located at any reasonable distance from the manufacturing apparatus—completely isolated, if the product is inflammable. All fire risk thus can be avoided. The circulating oil is of the most importance and must have no free-carbon or inflammable distillate at 600 deg. F. Its copyrighted name is "meprolene."

Meprolene has very high flash and fire tests. It withstands high temperatures for indefinite periods. It

JACKETED MELTING KETTLES AND MEPROLENE LINES

trolling temperature, poor heat distribution and fire menace. Saturated steam did not provide high enough temperature ranges, so attention was turned toward superheated steam. The difficulties encountered with

does not carbonize, distill or "crack." It is made especially for use in this process.

The absorber is of peculiar design and consists of the heating element, which is built into a brick furnace. It has a dutch oven extension and is strongly reinforced by steel framework. The heating element is made of two-inch boiler tubes expanded into cast headers of heavy design. It is divided into one or more paths of flow to insure current consistent with maximum efficiency and heat transfer. Heavy plugs are screwed in the headers opposite the ends of each tube which permit of easy access to the inside of the tubes for cleaning. Cleanout doors in the furnace walls and insulated steel doors at each end of the absorber are easily removed and expose the entire heating element. Either fuel oil or gas can be used for heating.

The circulating equipment includes a Kinney positive displacement rotary pump, usually motor driven through silent gearings, the pump and motor being mounted on a unit sub-base.

Pipe mains and all meprolene circulating lines are of standard weight steel pipe and, with the exception of the smaller sizes, have flanged connections. The flanges are made of forged steel and welded to the pipe. The gaskets used on the flanges are made for service in this class of work. Patented automatic valves give thorough protection from damage that might otherwise result from negligence or improper handling. These valves automatically shut off the fuel from the burners if there is any interruption to the flow of the meprolene or of compressed air when air atomizing oil burners are used. Other automatic devices can be attached to shut down the system if it is damaged by an external source.

Two accompanying photographs show a typical installation of the Merrill system of heat transmission, and two melting kettles which are part of a battery of six. At the particular plant where this system is installed, it was intended to use superheated steam for heating these kettles. The equipment was installed with all piping connections, valves, insulation, superheater, etc., but after several months had been spent in an endeavor to use superheated steam, this method was abandoned, as the superheating equipment could not furnish heat enough for even one kettle. The quantity of steam necessary was so great that it was decided to be entirely impracticable, if not impossible, to use it.

The photograph of the system shows a standard absorber with a normal heat output of 800,000 B.t.u. per hour, a circulating pump with a capacity of 160 g.p.m., a 10-hp. motor and all necessary accessories such as gages, thermometers, automatic valves, etc. This machinery is installed in a one-story building outside of the manufacturing plant. The floor space of this building is about 16 x 26 ft. City gas is used for fuel.

The battery of melting kettles is located on the third floor of the manufacturing building. They are approximately 5 ft. in diameter, 5½ ft. deep, open top, glass enamelled and equipped with agitators. The kettles have a jacket space of about three inches around the entire sides and bottom. Meprolene is circulated through four-inch pipe mains coming up from the absorber room. The meprolene enters the jackets at the bottom and exits from the top, returning to the absorber to be reheated. These kettles are used in the manufacture of a com-

pound the ingredients of which are charged into them at room temperature. These materials are fused and heated to 380 deg. F. The weight of a charge is three tons and the material has an average specific heat of 0.74, which includes the latent heat of fusion. After the compound has liquefied, 1700 pounds of water is added and this is raised from 60 to 212 deg. F. and completely evaporated in the process. This work is performed in about three and one-half hours time. The

KINNEY PUMP, ABSORBER AND CONTROL DEVICES

meprolene enters the jackets at 500 deg. F. and returns to the absorber at 475 deg. F. thus having a 25-deg. gradient.

In another manufacturing plant, batches of 3000 pounds of asphalt are being melted. The hot product is used in open pans for saturating purposes.

Three U-shaped jacketed kettles and ten long U-shaped jacketed saturating pans comprise the equipment.

As first installed, steam at 125 pounds pressure was the source of heat. High pressure in the jackets caused strains resulting in constant leaks, and soon the insulation was ruined. The absence of insulation made the room temperature unbearable in summer as well as increasing the fuel cost.

Steam at 125 pounds pressure has a corresponding temperature of 345 deg. F. The mixture required 300 deg. F. The thermic head was but 45 deg. F. With everything working as well as possible, the heat transfer was slow, but frequent delays caused by leaks, bothersome steam traps and reducing valves made production uncertain. The passing of the product to be coated through the saturating pans absorbed the heat so rapidly that frequent stops were necessary to permit the temperature to rise to a workable point again. Even with the highest attainable steam pressures uniformly good quality of product was not obtained.

The identical equipment now operates on a Merrill oil circulating system at 475 deg. F. The pressure is now but 14 pounds. Ample thermic head has assured steady production. Reduced pressure has stopped leaks. New insulation makes the work room more comfortable. The time of melting a batch is now thirteen hours as compared to thirty-two hours required with steam. The production decidedly increased, although there are 35 per cent fewer operatives employed.

Other installations have been made in a number of the leading plants throughout the country, and are used in the manufacture of chemicals, dyes, rubber wire insulation, roofing felt saturation, metal and paper coating and other industries were high constant temperatures and controllable heat are required.

These systems are built in a number of standard sizes, ranging in size from 50,000 to 1,300,000 B.t.u. per hour. Capacities greater than this are taken care of by connecting the absorbers in battery.

### Soldier Chemists Back to Industry

When the United States entered the European war one of the first problems to be considered was the effect of the draft upon essential industries. It was early appreciated that in order to maintain full efficiency it would be necessary to conserve as far as possible skilled workers and men with technical training. In order that we might not suffer from the depletion of our ranks, steps were taken to secure deferred classification and later on provision was made to furlough back to industry. This arrangement made it possible for chemical industries to maintain their efficiency and has contributed largely to the effectiveness of our forces in the field.

Up to the time of cessation of hostilities the Industrial Relations Branch of the Chemical Warfare Service had recommended for deferred classification 641 chemists and skilled workers. These recommendations were favorably considered, as a rule, by the Local Boards, and as a result about 90 per cent of the men so recommended were put in a deferred class. Many cases, however, were not brought to the attention of this branch until the men had actually been called into service. Such chemists or skilled workers as were essential to industry were then furloughed in order that the production of war materials might not be retarded. Through this method 156 men had been returned to industry, and at the time of the signing of the armistice 120 more cases were pending in the Adjutant General's Office.

As hostilities cease we naturally must again turn to peace-time conditions and look forward to the future development of chemical industry in America. The problem now before the Industrial Relations Branch of the Chemical Warfare Service is to assist chemists in service to secure positions where their training and experience can be used to the best interests of the Government. This enormous readjustment is rendered possible through the information gathered by Dr. Charles L. Parsons, secretary of the American Chemical Society, and through the questionnaires sent out by Major F. E. Breithut of the Personnel Division of the Chemical Warfare Service.

In order to accomplish results the chemists now in military service who desire to return to chemical industry are being requested to inform the chief of the Industrial Relations Branch concerning their future prospects, while the manufacturers are being asked to designate their requirements for chemists. The administration of this work will be carried out by the Industrial Relations Branch so that any information desired may be obtained by writing to Major Allen Rogers, Chief, Industrial Relations Branch, Chemical Warfare Service, 7th and B Streets, N. W., Washington, D. C.

### Société de Chimie Industrielle

Secretary Charles A. Doremus announces that a meeting of the New York Section of the Société de Chimie Industrielle will be held in Rumford Hall, 50 East 41st Street, on Tuesday evening, Nov. 19, beginning promptly at 8.30 o'clock.

The program for the evening will be: "Industrial Efforts in France During the War," Georges Maoussa, Docteur ès Sciences, member of the French High Commission; "The Electrochemical Industries in France," C. O. Mailloux, E.E., M.S., D.Sc., past president of the American Institute of Electrical Engineers; member of the American Industrial Committee to France; General Discussion of Ways and Means for Insuring the Further Development of the Société de Chimie Industrielle.

### \$100 Reward

A reward of \$100 is offered for the recovery of the platinum dishes and crucibles answering the following descriptions stolen from the Kentucky Agricultural Experiment Station, Lexington, Ky., during the week following Oct. 17, 1918, or for information leading to the conviction of the thief:

Platinum crucibles—No. 2, weighing 11.9750 grams, No. 3, 11.9703 grams, No. 10, 16.0273 grams, No. 13, 8.4319 grams, No. 18, 15.8232 grams, No. 22, 15.7905 grams, No. 26, 15.7580 grams, one not numbered, 18.9431 grams. Platinum dishes—No. 1, weighing 46.4689 grams, No. 11, 32.6709 grams, No. 12, 33.0927 grams, No. 14, 49.1097 grams, No. 15, 48.6788 grams, No. 20, 48.5347 grams, No. 22, 48.3856 grams, No. 23, 47.2223 grams.

## Personal

DR. ARTHUR L. DAY has presented his resignation as director of the Geophysical Laboratory, Carnegie Institution of Washington, effective Oct. 1, 1918, and will take up research on glass and allied materials for the Corning Glass Works in Corning, N. Y. Dr. Day has been director of the laboratory since its establishment in 1906, having been previously engaged in silicate researches at the U. S. Geological Survey in 1904 and 1905.

MR. F. N. FLYNN has resigned as general superintendent of the smelting and refining departments of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail, B. C.

MR. L. H. GOEBEL is now associated with the engineering staff of Wallace & Tiernan Co., manufacturers of chlorine control apparatus and sanitary engineering specialties. He was formerly superintendent of filtration and chief chemist of the Water Filtration Plant of the Union Stock Yard & Transit Co., Chicago, Ill.

DR. ALCAN HIRSCH, chemical engineer of New York City, recently married Miss Edith D. Borg.

MR. DORSEY A. LYON of the U. S. Bureau of Mines has been placed in charge of the Pittsburgh Station as well as the other ten experimental stations of the Bureau. His headquarters will be in Pittsburgh.

MR. NATHAN OWITZ, for the past four years general manager of the J. P. Devine Co., Buffalo, N. Y., has resigned to accept the presidency and management of the Persol Chemical Corp., which he recently organized.

MR. CHARLES D. TEST, formerly chemist for the Western Potash Works of Antioch, Neb., has accepted a position on the staff of the United States Tariff Commission.

MR. B. H. TRIPP has been appointed district manager of sales for the Pacific Coast territory of the Chicago Pneumatic Tool Co. of Massachusetts. His office will be in San Francisco, Cal.

MR. WILLIS WERNER has been appointed chief chemist of the Republic Iron & Steel Co., Youngstown, Ohio. He will have charge of the blast furnace and open-hearth laboratories.

MR. F. W. BRUCKMILLER is now chemist for the Standard Oil Co. (Indiana), at Sugar Creek, Mo. He was formerly assistant professor of chemistry at the University of Kansas.

MR. ARTURO R. CALVO, for the past five years manager of sales of the Permutit Co., has resigned to become an officer and director of the Hercules Engineering Corporation and its affiliated interests, the Electrolytic Engineering Corporation and the Technical Products Co.

MR. FRANK D. CARNEY, chief metallurgist, and LEWIS B. LINDEMUTH, superintendent of the crucible and electric furnace departments of the Bethlehem Steel Co., Bethlehem, Pa., resigned their positions on Nov. 1 and have formed the partnership of Carney & Lindemuth, consulting engineers in iron and steel metallurgy and practical steel works operation, with offices at 40 Wall St., New York City.

MR. BENTON DALES is now research chemist for the B. F. Goodrich Co., Akron, Ohio, having formerly been head of the chemistry department of the University of Nebraska.

MR. ANDREW M. FAIRLIE, consulting chemical engineer, announces the opening of an office for general consulting practice at 1204 Third National Bank Building, Atlanta, Ga. Mr. Fairlie, who has been for several years chemical engineer for the Tennessee Copper Co., is still retained by that company in a consulting capacity.

PROFESSOR H. F. MOORE of the Engineering Experiment Station of the University of Illinois, Urbana, Ill., has been appointed, by the National Research Council, chairman of the committee to investigate the fatigue phenomena of metals.

MR. WILLIAM E. PULIS and MR. NATHAN M. CLARK have been elected vice-presidents of the Celluloid Co., 36 Washington Place, New York.

MR. RUSH T. SILL of the firm of Sill & Sill, consulting mining and metallurgical engineers, has received a commission as Captain of Engineers and is reporting at Fort Douglas.

MR. F. E. SMITH has accepted the position as chief engineer with the Barber-Greene Co., Aurora, Ill. Mr. Smith was formerly of the engineering department of the Stephens-Adamson Mfg. Co. and of the American Zinc & Chemical Co.

MR. R. H. WILSON has been appointed by the Walter A. Zelnicker Supply Co. as assistant to the president with an office at St. Louis. Mr. Wilson has been with the company for some time, latterly as Houston representative.

ing developed and introduced machinery and methods which are still in use in these industries. He was the inventor of the lead-zinc storage battery, and the first to commercially apply the storage battery to the propulsion of street cars. For many years he had resided in or near New York City, engaging in the profession of consulting chemist, and had also been widely employed as an expert in cases before the courts, involving complicated scientific and engineering questions. A veteran artilleryist of the Civil War, he had devoted his attention, since the entry of the United States into the present war, to the problem of accurate sighting of anti-submarine guns carried by aeroplanes and to chemical problems vital to the interests of our country in the war. He was a charter member of the American Society of Mechanical Engineers and of the American Electrochemical Society and a member of the American Chemical Society, the Society of Chemical Industry of Great Britain and various other scientific and literary bodies.

## Current Market Reports

### The Non-Ferrous Metal Market

**Thursday, Nov. 7.**—The non-ferrous metal market is likely not to alter immediately from its steady course at any single period during the prospective transition from a war basis to regular industrial pursuits. Antimony alone is declining, because the producers are forcing the market slightly to consume their offerings.

**Aluminum.**—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminum, 18 ga. and heavier, 42c.; powdered aluminum, 100 mesh, 70c.

**Antimony.**—Antimony continues to decline, not having a strong demand. Prices are between 9c. and 9½c. per pound.

**Chrome.**—Western production is now in slight excess of demand. The nominal quotation for 40 per cent ore is \$1.40 per unit, while 50 per cent ore is bringing \$1.70.

**Copper.**—The price of \$520 per ton for carload lots and 27.3c. per pound for small quantities was continued for another period at the conference held on Oct. 25 at Washington.

|                                 |     |        |          |
|---------------------------------|-----|--------|----------|
| Copper sheets, hot rolled.....  | lb. | \$0.36 | —\$0.37½ |
| Copper sheets, cold rolled..... | lb. | .37    | — .38½   |
| Copper bottoms.....             | lb. | .43    | — .45    |
| Copper rods.....                | lb. | .36    | — .37    |
| Copper wire.....                | lb. | .29    | — .30    |
| High brass wire.....            | lb. | .28    | — .29½   |
| High brass sheets.....          | lb. | .28    | — .29    |
| High brass rods.....            | lb. | .26    | — .28    |
| Low brass wire.....             | lb. | .32    | — .34    |
| Low brass sheets.....           | lb. | .32    | — .34½   |
| Low brass rods.....             | lb. | .32    | — .35    |
| Brazed brass tubing.....        | lb. | .37    | — .39    |
| Brazed bronze tubing.....       | lb. | .42    | — .44½   |
| Seamless copper tubing.....     | lb. | .41    | — .43    |
| Seamless bronze tubing.....     | lb. | .45    | — .46    |
| Seamless brass tubing.....      | lb. | .37½   | — .39½   |
| Bronze (gold) powder.....       | lb. | 1.00   | — 1.75   |

**Lead.**—The lead market is limited by selling restrictions, the supply being allocated by the Lead Committee. In carload lots at East St. Louis, the price is \$155 per ton. In New York all speculative and traders' lead has disappeared. The Lead Committee apportions lead at 8.05c. to legitimate consumers.

**Manganese.**—The scale prices on page 629 of CHEMICAL & METALLURGICAL ENGINEERING, June 15, prevail; the highest price per unit being \$1.35.

**Silver.**—Due to the flow of silver to Asia in payment for munitions and the greatly increasing industrial consumption in photography, motion picture reels and silverware, there is a shortage of silver even at the present Government price of \$1.01½ per ounce.

**Tin.**—The Tin Committee of the American Iron and Steel Institute has not yet announced the official price on tin. No doubt an understanding will have to be had with the producers before a final statement can be made public and as they are all in distant foreign countries, considerable

## Obituary

MR. WINTHROP R. CADY, sales manager of the Colorado Iron Works Co., died in Salt Lake City on Friday, Oct. 25, of pneumonia, following influenza at the age of 31. Mr. Cady had a record of seventeen years' continuous service with the Colorado Iron Works Co., and had a wide acquaintance among metallurgists and mining men of the West.

LIEUT.-COL. HARRISON, controller of the chemical warfare division of Great Britain, died of pneumonia Nov. 6. Lieut.-Col. Harrison took a leading part in the development of protective apparatus against gas attacks.

PROFESSOR WILLIAM MAIN, scientist and engineer, and formerly professor of chemistry in the University of South Carolina, died recently at his home in Piermont, N. Y., in his 74th year. He established the first assay office in the State of Colorado in 1866 and was one of the pioneers of the copper and lead mining industries of this country, hav-

time will elapse in intercommunication. During November 3575 tons entered our Pacific ports and 685 tons entered our Atlantic ports. The price is around 78c. lb., but there are no open transactions.

**Tungsten:**—The Western producers of scheelite are reluctant in offering at \$26 per unit. High grade wolframite is bringing \$25. Off-grade ores vary from \$20 to \$24.

**Zinc:**—Spelter is tending to decline slightly. East St. Louis is quoting \$173 per ton for spot, November delivery, \$174, December \$179, and January \$166. Zinc dust, 13¢ to 16c. per lb. Sheet zinc, 15c. per lb.

The Iron and Steel Market

The absorbing question before the iron and steel trade is the course of events in the market during the transitional period from war-time to peace-time conditions. For the longer future, the almost unanimous opinion is there will be heavy demand for iron and steel and at quite remunerative prices, but there must of necessity be a transitional period while the market finds itself or has the level found for it. Steel, in the final analysis, is used chiefly for construction purposes, money being invested in expectation of returns over a period of years. Some buyers of steel are justified simply in paying the current market price from week to week or month to month, but investment buying cannot proceed on that policy. There may be such a market decline in construction costs in three months as would equal the return on investment for several years, hence the investment buyer of steel must await settled conditions.

While the authorities at Washington have given to the press some intimations that cancellations of war contracts will be more or less gradual, it goes without saying that as to many items of war steel it would be a woeful waste of money to allow manufacture to continue a day longer than really necessary in the interest of maintaining conditions during the discussion and settlement of peace questions. There has been a tremendous production of shell steel and likewise a tremendous consumption of shells. When the consumption ceases the production should cease, because even at that the material in transit and in course of manufacture represents a very large stock of shells.

The authorities have made it clear to holders of large contracts that may be cancelled that the contractors will be treated fairly and that they will suffer no actual loss. The plan worked out, although not publicly announced, is that all material completed will be accepted and paid for, and all material in course will be purchased at a valuation including a pro rata of profit against the total profit that would accrue on the completed material. Material in course will be interpreted to include not only material in actual process of manufacture, but material definitely acquired for the purpose of filling the contract. Having purchased such material, the Government will sell it in the best market, in most cases doubtless to the contractor himself.

CONTROL IN TRANSITIONAL PERIOD

Several weeks ago it was plainly intimated that the War Industries Board desired to continue its regulation of industry after the termination of hostilities, for the purpose of protecting industry from violent reaction and establishing a permanent basis upon which industry could go ahead for the years of work that are to follow the war. Since then there has been active work on plans looking to the continuance of activity of various Government agencies for a period, perhaps six months, after the President's peace proclamation. The War Industries Board and the Food and Fuel Administrations would terminate upon the official declaration of peace. The Railroad Administra-

tion is legally empowered to continue for 21 months thereafter, while the Shipping Board continues indefinitely, and its present program, which it has announced lately is not to be altered, covers 15,000,000 tons deadweight of vessels, of which about 2,500,000 tons has thus far been built. A committee has been established to formulate a plan for the continuance of various control activities, and it is practically stated that such legislation as appears desirable will be sought from Congress. Apart from extension of the time limit of these activities, it is important that the relationship between the contemplated activities of the War Industries Board and the Sherman law should be established. As to iron and steel, the board has agreed with the producers upon certain maximum price limits, which could not be interpreted as in violation of the Sherman law, even if it had not been laid on the shelf or had something else done with it for the period of the emergency. The great majority of the trade, however, feels that what is to be needed for the next few months at least is the fixing of minimum prices, and if the board agrees with the producers on minimum prices, that constitutes an agreement also among the producers themselves, possibly quite another matter in the eyes of the Sherman law.

While there have been some clear evidences that some steel can be sold for export at prices above the Government limits, and it appears even that some such export orders have been booked, it is practically the unanimous opinion that if left to itself the domestic market in iron and steel would in no great while suffer a very severe slump while buyers were waiting for a stable market to be established. The familiar course, as exemplified over and over again in steel market history, is for prices to drop very sharply and to a level much below that which is subsequently established as a safe trading basis for all concerned. On the whole such disorganization is very undesirable, and it is undesirable to the Government, which expects to collect heavy taxes. There is a small minority in the trade that would probably welcome a slump, in expectation of its affording means for general reductions in cost of production, including reductions in wages. A couple of years ago such a view was indeed the common one, but meanwhile evidence has accumulated that a universal and heavy decline in wages and commodity prices cannot be expected, hence there has lately been very much less desire for a "shake-out" after the war than there was some time ago.

DIRECT GOVERNMENT INFLUENCE

That the Government will directly have great powers to exercise an influence upon steel prices is obvious, on account of the large purchases to be made for a long time to come by the Shipping Board and the Railroad Administration. It has lately become quite clear that the Government fully intends to exercise its power, that no purchases will be made that could afterward be called in question as representing an unwise use of public funds. For instance, the Railroad Administration has refused to approve the prices of \$55 and \$57 for bessemer and open-hearth rails agreed upon last September between the War Industries Board and the rail makers, and points out that the average price on rails bought by the roads long ago and still undelivered is about \$36. A dozen or more railroads protested against being required to accept freight cars allotted them from the 100,000 cars ordered by the Railroad Administration, asserting that the cars should be bought from the revolving fund and afterward sold to the railroads at something like peace-time prices. These protests have been overruled by the Railroad Administration, but subsequent purchases, which undoubtedly must be made, will naturally be at as low prices as can be compassed. Again, the Shipping Board has decided, although official announcement does not seem to have been made, to cut down the weekly plate allotment of 50,000 net tons for account of the Fleet Corporation to an amount not exceeding the actual flow of plates into hulls. A surplus of about a million tons has accumulated, representing a factor of safety when every possible ship counted, no matter what the expense, but too expensive to maintain for peace times. The 50,000

tons a week is equal to about 700,000 tons deadweight of vessels per month, while the actual rate of construction has averaged between 300,000 and 400,000 tons a month for several months past. The Director General of Shipbuilding has lately stated that 700,000 tons a month is the objective and that it is expected to be attained next spring. In the interim the plate quota will be reduced, by perhaps between 30 and 50 per cent, and the million-ton surplus may also be reduced, so that 50,000 tons a week of plates may not be called for again altogether as soon as vessel construction reaches 700,000 tons deadweight a month.

Thus the Railroad Administration and the Shipping Board will be able to exert a powerful influence toward a general reduction in steel prices, while on the other hand, when these Government instrumentalities purchase for peace times steel at certain prices, those prices will have considerable standing with the trade at large; and with the influence of the War Industries Board, together with such additional powers as may be granted it, there is opportunity promised for a safe and reasonable readjustment in iron and steel prices.

### The Chemical Market

**HEAVY CHEMICALS:**—The past two weeks have shown considerable lack of activity, with few transactions of note, other than the usual trading that is in evidence. Medicinal products were in strong demand and in most instances prices have had an upward tendency, while some of the other products that come under this heading were shaded in prices. One of these was caustic soda, which has developed a rather weak position, in view of the lack of buying interest, while its allied product, soda ash, has been more firm, although conditions relative to this material in the West and Middle West have not been so favorable.

**Bichromate of Soda:**—There has been continued inactivity in this market and the position of the item is apparently gaining no strength. In spite of the frequent cheap offerings that appear on the market there is a very noticeable lack of interest. At the close some sales were made at 19½c. for the standard brands, and most factors are now quoting at that figure.

**Soda Ash:**—A rather firm situation prevails in the East for this item where bag material is in strong demand, but barrels are more or less neglected, particularly so in the West and Middle West, where prices have been on the decline during the latter part of the past two weeks. Single bag material in New York was generally quoted at from \$2.65 to \$2.70, while in Chicago offerings were made at \$2.60. Double bags in the Middle West were held at \$3, while barrel material was offered at \$2.85, though in New York prices ranged from \$3.10 to \$3.15.

**Bleaching Powder:**—While stocks of this material are none too free for civilian consumption, the persistent demand that has been in evidence for a long period has eased up considerably during the latter part of the past two weeks. Some sales were consummated at 7c., though offerings at the close were heard as low as 6½c., with the general range of prices being 6½c. to 6½c.

**Caustic Soda:**—Considerable speculation is rife as to what the actual situation of this product may be, owing to the peculiar movement of late. However, most factors concede that its position is gradually weakening, particularly the solid material, while the ground seemingly maintains a more firm standing. Sales of the solid material are passing at some low levels, in some instances at \$4. Most factors now offer the 76 per cent solid at from \$4.15 to \$4.25, while the ground material is quoted at from \$5.15 to \$5.25.

**Bicarbonate of Soda:**—This market has developed a more steady tone and prices that have been soaring seemingly reached such an unusual mark that buyers were not disposed to meet. Consequently stocks have accumulated and prices declined from \$4.40 to \$4.25, which is still considered rather high.

**Quinine Sulphate:**—The Java brand, that has commanded considerable attention, also developed an easier position, but stocks are reported to be none too liberal in supply. Quotations generally heard range from \$1.04 to \$1.05.

**Citric Acid:**—Buyers have been showing very little interest at the close and prices therefore have declined from \$1.23 to \$1.15. Spot prices are now quoted at from \$1.15 to \$1.16 for the crystal material, and the powdered is offered at \$1.10.

**Yellow Prussiate of Potash:**—There has been a continued depreciation in price, with material liberally offered in many directions. Buyers have been showing very little interest in the material, in spite of the unusually cheap offerings, some being as low as 90c., while other quotations range from 95c. to \$1.

**COAL TAR PRODUCTS:**—During the interval no important price changes were noted for most of the intermediates, and where some were effected they were inclined upward. Trading in general has been rather quiet, but in view of this fact most of the products are in scarce supply. Para-aminophenol is one of the items which command considerable interest and may be safely classed as the feature of the products that come under this heading. Paraphenylenediamine is also in strong demand and stocks are reported to be in a somewhat depleted condition, while the position of paranitraniline is a trifle easier in stocks.

**Phenol:**—A rather firm situation prevails for this material, although the pronounced demand that has been in evidence for export purposes has slackened up considerably, particularly trading in the Far East. Local requirement is rather strong and trading is of sufficient volume to keep the market firm. Material with affidavit attached is held at 2c. more than for that of more recent manufacture.

**Benzol:**—Nothing of an important character has developed in this market. The item maintains a rather firm position and trading is of sufficient volume to take the slack off the market. Available material is fully in proportion to the current demand. Prices for the product in tank cars are subject to no change, though a slight increase is noted for drum material.

**Metatolulenediamine:**—Very little of the product is being offered; however, the consumption demand is not pressing, and in view of this fact the situation is being fairly well met. Prices are quotably unchanged.

**Para Amidophenol:**—There has been a continued depreciation in stocks and some important factors state they are in no position to offer, other than in occasional small quantities. Both the base material and H.C.L. are in firm demand, but quotations generally heard indicate no material change in prices.

**Benzidine:**—The only pronounced interest in this item is for the base material, which is being purchased quite freely for export purposes, while the local consumption is rather slow. The sulphate is more or less neglected with very little buying interest noted. Neither of the items has been affected by price changes.

**Saccharines:**—A peculiar situation continues to persist in this market, with the prospects small for any activity at the moment. A recent meeting held in New York City for the purpose of encouraging more interest in the item has apparently developed nothing particularly favorable up to the present writing. Prices have declined \$1 to \$2 and as much as \$3 in some instances for both the soluble and insoluble, which are now on a parity.

**H. Acid:**—Inquiry for this material continues to be very persistent and trading therefore is active. However, most factors in this line still report stocks very scarce, although more frequent offerings appear on the market. Prices are quotably unchanged and remain at firm levels.

**Aniline Oil:**—Due to the strong demand that has been prevailing for this material during the past few weeks, most directions state that stocks are in a depleted condition and very few spot offerings are now heard. A general advance in price of 1c. to 2c. has been made.

**Dinitrophenol:**—Offerings of this material for civilian consumption are no easier and the occasional lots which appear in the resale market originate considerable interest. But these are held at rather high prices, which apparently does not curtail trading.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET NOV 8, 1918

|                                                      |         |               |   |        |
|------------------------------------------------------|---------|---------------|---|--------|
| Acetic anhydride.....                                | lb.     | 1.60          | — | 1.85   |
| Acetone.....                                         | lb.     | .25           | — | .25    |

| Acetic, 36 per cent.....                             | cwt.    | 10.76         | — | 10.87  |
| Acetic, glacial, 99 1/2 per cent, carboys.....       | cwt.    | 19.00         | — | 19.20  |
| Boric, crystals.....                                 | lb.     | .13           | — | .15    |
| Citric, crystals.....                                | lb.     | 1.10          | — | 1.15   |
| Hydrochloric, C. P.....                              | lb.     | .08           | — | .08    |
| Hydrofluoric, 30 per cent, in barrels.....           | lb.     | .15           | — | .16    |
| Lactic, 44 per cent.....                             | lb.     | .05           | — | .07    |
| Lactic, 22 per cent.....                             | lb.     | .06           | — | .07    |
| Molybdic, C. P.....                                  | lb.     | 6.00          | — | 7.40   |
| Nitric, 36 deg.....                                  | lb.     | .08           | — | .10    |
| Nitric, 42 deg.....                                  | lb.     | .04           | — | .04    |
| Oxalic, crystals.....                                | lb.     | .40           | — | .43    |
| Phosphoric, 47-50 per cent paste.....                | lb.     | .07           | — | .10    |
| Phosphoric, ref. 50 per cent.....                    | lb.     | .35           | — | .40    |
| Picric.....                                          | lb.     | .75           | — | .85    |
| Pyrogallol, resublimed.....                          | lb.     | 3.25          | — | 3.50   |
| Sulphuric, 60 deg.....                               | ton     | 16.00         | — | 16.00  |
| Sulphuric, 66 deg.....                               | ton     | 25.00         | — | 25.00  |
| Sulphuric, oleum (Fuming), tank cars.....            | ton     | 60.00         | — | 65.00  |
| Tannic, U. S. P., bulk.....                          | lb.     | 1.40          | — | 1.50   |
| Tartaric, crystals.....                              | lb.     | .86           | — | .95    |
| Tungstic, per lb. of W.....                          | lb.     | 1.70          | — | 1.75   |
| Alcohol, sugar cane, 188 proof.....                  | gal.    | 4.91          | — | 5.00   |
| Alcohol, wood, 95 per cent.....                      | gal.    | .91           | — | .92    |
| Alcohol, denatured, 180 proof.....                   | gal.    | .68           | — | .69    |
| Alum, ammonia lump.....                              | lb.     | .06           | — | .06    |
| Alum, chrome ammonium.....                           | lb.     | .18           | — | .19    |
| Alum, chrome potassium.....                          | lb.     | .22           | — | .22    |
| Alum, chrome potassium.....                          | lb.     | .12           | — | .13    |
| Alum, potash lump.....                               | lb.     | .09           | — | .10    |
| Aluminium sulphate, technical.....                   | lb.     | .02           | — | .02    |
| Aluminium sulphate, iron free.....                   | lb.     | .03           | — | .04    |
| Ammonia, 28 deg., carboys.....                       | lb.     | .08           | — | .09    |
| Ammonia, anhydrous.....                              | lb.     | .08           | — | .08    |
| Ammonium carbonate.....                              | lb.     | .12           | — | .13    |
| Ammonium nitrate.....                                | lb.     | .12           | — | .15    |
| Ammonium, sulphate domestic.....                     | lb.     | .07           | — | .08    |
| Amyl acetate.....                                    | gal.    | 5.30          | — | 5.35   |
| Arsenic, white.....                                  | lb.     | .09           | — | .13    |
| Barium carbonate, 99 per cent.....                   | ton     | 80.00         | — | 90.00  |
| Barium carbonate, 97-98 per cent.....                | ton     | 65.00         | — | 67.00  |
| Barium chloride.....                                 | ton     | 70.00         | — | 80.00  |
| Barium sulphate (Blanc Fixe, Dry).....               | lb.     | .04           | — | .05    |
| Barium nitrate.....                                  | lb.     | .12           | — | .14    |
| Barium peroxide, basis 70 per cent.....              | lb.     | .30           | — | .32    |
| Bleaching powder, 35 per cent chlorine.....          | lb.     | .06           | — | .07    |
| Borax, crystals, sacks.....                          | ton     | .08           | — | .08    |
| Bromine, crude.....                                  | ton     | 65.00         | — | 70.00  |
| Bromine, technical.....                              | lb.     | .75           | — | .75    |
| Calcium acetate, crude.....                          | lb.     | .04           | — | .05    |
| Calcium, carbide.....                                | lb.     | .16           | — | .17    |
| Calcium chloride, 70-75 per cent, fused, lump.....   | ton     | 22.00         | — | 24.00  |
| Calcium peroxide.....                                | lb.     | .50           | — | 1.70   |
| Calcium phosphate.....                               | lb.     | .12           | — | .23    |
| Calcium sulphate, 98-99 per cent.....                | lb.     | .09           | — | .09    |
| Carbon bisulphide.....                               | lb.     | .08           | — | .09    |
| Carbon tetrachloride, drums.....                     | lb.     | .60           | — | .70    |
| Carbonyl chloride (Phosgene).....                    | lb.     | 1.10          | — | 1.50   |
| Caustic potash, 88-92 per cent.....                  | lb.     | .67           | — | .72    |
| Caustic soda, 76 per cent.....                       | 100 lb. | 4.40          | — | 4.45   |
| Chlorine, liquid (Government Purchase).....          | ton     | (Fixed Price) | — | .07    |
| Coal oil.....                                        | lb.     | 1.60          | — | 1.65   |
| Copperas.....                                        | lb.     | .02           | — | .02    |
| Copper carbonate.....                                | lb.     | .30           | — | .31    |
| Copper cyanide.....                                  | lb.     | .75           | — | .78    |
| Copper sulphate, 99 per cent, large crystals.....    | lb.     | .09           | — | .09    |
| Cream of tartar, crystals.....                       | lb.     | .75           | — | .85    |
| Epsom salt, bags, U.S.P.....                         | 100 lb. | 3.62          | — | 3.90   |
| Formaldehyde, 40 per cent.....                       | lb.     | .02           | — | .03    |
| Glauber's salt.....                                  | lb.     | .63           | — | .65    |
| Glycerine, bulk, C. P.....                           | lb.     | 4.25          | — | 4.30   |
| Iodine, resublimed.....                              | lb.     | .13           | — | .15    |
| Iron oxide.....                                      | lb.     | .17           | — | .17    |
| Lead acetate, white crystals.....                    | lb.     | .15           | — | .18    |
| Lead arsenate (Paste).....                           | lb.     | .12           | — | .12    |
| Lead nitrate.....                                    | lb.     | .12           | — | .14    |
| Lith. are, American.....                             | lb.     | 1.50          | — | 2.05   |
| Lithium carbonate.....                               | lb.     | .16           | — | .17    |
| Magnesium carbonate, technical.....                  | lb.     | .14           | — | .15    |

| Sodium molybdate, per lb. of Mo.....        | lb.     | 2.50 | — | 3.00 |
| Sodium nitrate, 95 per cent.....            | 100 lb. | 4.12 | — | 5.00 |
| Sodium nitrite.....                         | lb.     | .27  | — | .30  |
| Sodium peroxide.....                        | lb.     | .35  | — | .45  |
| Sodium phosphite.....                       | lb.     | .35  | — | .40  |
| Sodium prussiate, yellow.....               | lb.     | .39  | — | .40  |
| Sodium silicate, liquid (60 deg.).....      | lb.     | .04  | — | .05  |
| Sodium sulphide, 30 per cent, crystals..... | lb.     | .07  | — | .08  |
| Sodium sulphide, 60 per cent, fused.....    | 100 lb. | .11  | — | .11  |
| Sodium sulphite.....                        | lb.     | .05  | — | .06  |
| Strontium nitrate.....                      | lb.     | .25  | — | .30  |
| Sulphur, chloride, drums.....               | lb.     | .07  | — | .08  |
| Sulphur dioxide, liquid, in cylinders.....  | lb.     | 1.50 | — | .40  |
| Sulphur, flowers, sublimed.....             | 100 lb. | 4.35 | — | 4.50 |
| Sulphur, roll.....                          | 100 lb. | 3.20 | — | 3.85 |
| Sulphur, sublimed.....                      | lb.     | .65  | — | .70  |
| Tin bichloride, 50 deg.....                 | lb.     | .38  | — | .29  |
| Tin oxide.....                              | lb.     | .18  | — | .20  |
| Zinc carbonate.....                         | lb.     | .15  | — | .15  |
| Zinc chloride.....                          | lb.     | .15  | — | .15  |
| Zinc cyanide.....                           | lb.     | .13  | — | .14  |
| Zinc dust, 350 mesh.....                    | lb.     | .02  | — | .04  |
| Zinc sulphate, American process XX.....     | lb.     | .04  | — | .06  |

## Coal Tar Products (Crude)

|                                             |      |               |   |       |
|---------------------------------------------|------|---------------|---|-------|
| Benzol, pure, water white.....              | gal. | .22           | — | .27   |
| Benzol, 90 per cent.....                    | gal. | .25           | — | .30   |
| Toluol, in tank cars.....                   | gal. | (Fixed Price) | — | 1.50  |
| Toluol, for non-military use, in drums..... | gal. | (Fixed Price) | — | 1.55  |
| Xylo, pure, water white.....                | gal. | .45           | — | .55   |
| Solvent naphtha, water white.....           | gal. | .18           | — | .25   |
| Solvent naphtha, crude, heavy.....          | gal. | .45           | — | .55   |
| Creosote oil, 25 per cent.....              | gal. | .45           | — | .55   |
| Dip oil, 20 per cent.....                   | gal. | .30           | — | .32   |
| Pitch, various grades.....                  | ton  | 8.00          | — | 20.00 |
| Carbolic acid, crude, 95-97 per cent.....   | lb.  | 1.05          | — | 1.10  |
| Carbolic acid, crude, 50 per cent.....      | lb.  | .60           | — | .65   |
| Carbolic acid, crude, 25 per cent.....      | lb.  | .35           | — | .38   |
| Creosol, U. S. P.....                       | lb.  | .19           | — | .20   |

## Intermediates, Etc.

|                                       |     |       |   |       |
|---------------------------------------|-----|-------|---|-------|
| Alpha naphthol, crude.....            | lb. | 1.00  | — | 1.10  |
| Alpha naphthol, refined.....          | lb. | 1.50  | — | 1.60  |
| Alpha naphthylamine.....              | lb. | .55   | — | .60   |
| Aniline oil, drums extra.....         | lb. | .30   | — | .32   |
| Aniline salts.....                    | lb. | .45   | — | .45   |
| Anthracene, 80 per cent.....          | lb. | .08   | — | .08   |
| Benzaldehyde (f.f.c.).....            | lb. | 4.25  | — | 4.50  |
| Benzidine, base.....                  | lb. | 7.00  | — | 8.00  |
| Benzidine, sulphate.....              | lb. | 1.40  | — | 1.45  |
| Benzoic acid, U. S. P.....            | lb. | 3.00  | — | 3.10  |
| Benzoyl chloride.....                 | lb. | 2.90  | — | 3.00  |
| Benzoyl chloride.....                 | lb. | 2.45  | — | 2.50  |
| Beta naphthol benzate.....            | lb. | 10.00 | — | 12.00 |
| Beta naphthol, sublimed.....          | lb. | .75   | — | .85   |
| Beta naphthylamine, sublimed.....     | lb. | 2.65  | — | 3.00  |
| Dichloro-benzol.....                  | lb. | 4.00  | — | 4.50  |
| Diethylaniline.....                   | lb. | .36   | — | .38   |
| Dinitro-benzol.....                   | lb. | .40   | — | .45   |
| Dinitrochlorobenzol.....              | lb. | .60   | — | .60   |
| Dinitrophenol.....                    | lb. | .65   | — | .65   |
| Dinitrotoluol.....                    | lb. | .55   | — | .60   |
| Dinitrophenol.....                    | lb. | .65   | — | .65   |
| Dimethylamine.....                    | lb. | 1.00  | — | 1.10  |
| Diphenylamine.....                    | lb. | 3.25  | — | 3.50  |
| H-acid.....                           | lb. | 1.85  | — | 2.05  |
| Metaphenylenediamine.....             | lb. | .09   | — | .10   |
| Monochlorobenzol.....                 | lb. | .11   | — | .12   |
| Naphthalene, flake.....               | lb. | 1.20  | — | 1.30  |
| Naphthalene, balls.....               | lb. | 1.00  | — | 1.10  |
| Naphthalene, acid, crude.....         | lb. | .45   | — | .50   |
| Naphthylamine, 98-sulphonie acid..... | lb. | .55   | — | .60   |
| Nitro naphthalene.....                | lb. | 6.50  | — | 7.00  |
| Ortho-amidophenol.....                | lb. | 1.00  | — | 1.10  |
| Ortho-dichloro-benzol.....            | lb. | .75   | — | .85   |
| Ortho-toluidine.....                  | lb. | 4.25  | — | 5.00  |
| Ortho-nitro-toluidine.....            | lb. | 15.00 | — | 20.00 |
| Para-amidophenol, base.....           | lb. | 1.85  | — | 2.05  |
| Para-amidophenol, II, C. L.....       | lb. | .15   | — | .20   |
| Para-dichloro-benzol.....             | lb. | 1.80  | — | 1.95  |
| Paranitraniline.....                  | lb. | 1.50  | — | 1.60  |
| Paranitro-toluidine.....              | lb. | 4.00  | — | 4.50  |
| Paraphenylenediamine.....             | lb. | 2.25  | — | 2.50  |
| Para toluidine.....                   | lb. | 4.25  | — | 5.00  |
| Phthalic acid anhydride.....          | lb. | 4.25  | — | 5.00  |
| Phenol, U. S. P.....                  | lb. | 4.00  | — | 5.00  |
| Resorcin, technical.....              | lb. | 7.50  | — | 8.00  |
| Resorcin, pure.....                   | lb. | 1.50  | — | 2.00  |
| Salicylic acid.....                   | lb. | .31   | — | .33   |
| Sulphanilic acid, crude.....          | lb. | 2.50  | — | 3.00  |
| Toluidine.....                        | lb. | .85   | — | .90   |
| Toluidine-mixture.....                | lb. | .85   | — | .90   |

## Petroleum Oils

Crude (at the Wells)

|                             |      |      |   |      |
|-----------------------------|------|------|---|------|
| Pennsylvania.....           | bbl. | 4.00 | — | 4.00 |
| Cornish, Ohio.....          | bbl. | 2.85 | — | 2.85 |
| Somerset, Ky.....           | bbl. | 2.60 | — | 2.60 |
| Wessex, Ohio.....           | bbl. | 2.68 | — | 2.68 |
| Indiana.....                | bbl. | 2.28 | — | 2.28 |
| Illinois.....               | bbl. | 2.22 | — | 2.22 |
| Oklahoma and Kansas.....    | bbl. | 2.22 | — | 2.22 |
| Caddo, La., light.....      | bbl. | 2.25 | — | 2.25 |
| Corsicana, Tex., light..... | bbl. | 2.25 | — | 2.25 |
| California.....             | bbl. | 1.35 | — | 1.57 |
| Gulf Coast.....             | bbl. | 1.90 | — | 1.90 |
| Mexican.....                | bbl. | 1.90 | — | 1.90 |
| Fuel Oil                    |      |      |   |      |
| New York.....               | gal. | .15  | — | .15  |
| Philadelphia.....           | gal. | .07  | — | .15  |
| Baltimore.....              | gal. | .07  | — | .10  |
| Pittsburgh.....             | gal. | 1.04 | — | 1.04 |
| Texas.....                  | bbl. | 1.85 | — | 2.35 |
| Los Angeles.....            | bbl. | 1.65 | — | 1.65 |

| Gasoline (Wholesale) |      |        |        |
|----------------------|------|--------|--------|
| New York, motor      | gal. | 24 1/2 | —      |
| Gas machine          | gal. | 24 1/2 | —      |
| 72-76 degrees        | gal. | 33 1/2 | 39 1/2 |
| 70-72 degrees        | gal. | 32 1/2 | 37 1/2 |
| 67-70 degrees        | gal. | 30 1/2 | 36 1/2 |
| Pittsburgh, motor    | gal. | 25 1/2 | 26 1/2 |
| Chicago, motor       | gal. | 22 1/2 | 23 1/2 |
| Oklahoma, motor      | gal. | 21 1/2 | 22 1/2 |
| San Francisco, motor | gal. | 20 1/2 | 21 1/2 |

### Paraffine Waxes

|                              |     |        |        |
|------------------------------|-----|--------|--------|
| Crude, 103 to 105 deg. m.pt. | lb. | 08 1/2 | —      |
| Crude, 118 to 120 deg. m.pt. | lb. | 09 1/2 | —      |
| Crude, 124 to 126 deg. m.pt. | lb. | 10     | —      |
| Refined, 120 deg. m.pt.      | lb. | 13 1/2 | —      |
| Refined, 128 deg. m.pt.      | lb. | 14 1/2 | —      |
| Refined, 135 deg. m.pt.      | lb. | 16     | 16 1/2 |
| Ozokerite, brown             | lb. | 75     | 80     |
| Ozokerite, green             | lb. | 85     | 90     |

### Lubricants

|                                              |      |    |    |
|----------------------------------------------|------|----|----|
| Black, reduced, 29 gravity, 25-30 cold test. | gal. | 24 | 25 |
| Cylinder, light                              | gal. | 39 | 50 |
| Cylinder, dark                               | gal. | 39 | 43 |
| Paraffine, high viscosity                    | gal. | 40 | 41 |
| Paraffine, 0.903 sp. gr.                     | gal. | 36 | 38 |
| Paraffine, 0.885 sp. gr.                     | gal. | 26 | 28 |

### Flotation Oils

(Prices at New York unless otherwise stated)

|                                                                   |      |    |    |
|-------------------------------------------------------------------|------|----|----|
| Pine oil, crude, f. o. b. Florida                                 | gal. | 44 | —  |
| Pine oil, steam-distilled, sp. gr. 0.925-0.940                    | gal. | 58 | 60 |
| Pine oil, destructively distilled                                 | gal. | 58 | 60 |
| Pine-tar oil, sp. gr. 1.02-1.035                                  | gal. | 35 | —  |
| Pine-tar oil, double refined, sp. gr. 0.965-0.990                 | gal. | 42 | —  |
| Pine-tar oil, ref., light, sp. gr. 0.950, tank cars, f.o.b. works | gal. | 37 | —  |
| Pine-tar oil, ref., heavy, sp. gr. 1.025, tank cars, f.o.b. works | gal. | 28 | —  |
| Pine-tar oil, ref., thin, sp. gr. 1.060-1.080                     | gal. | 32 | —  |
| Turpentine, crude, sp. gr. 0.870-0.900                            | gal. | 45 | —  |
| Hardwood oil, f.o.b. Michigan, sp. gr. 0.960-0.990                | gal. | 23 | —  |
| Hardwood oil, f.o.b. Michigan, sp. gr. 1.06-1.08                  | gal. | 23 | —  |
| Wood creosote, ref., f.o.b. Florida                               | gal. | 31 | —  |

### Naval Stores

|                                          |          |       |       |
|------------------------------------------|----------|-------|-------|
| Rosin A-E barrel                         | 280 lb.  | 15.35 | 15.65 |
| Rosin F-I                                | 280 lb.  | 15.65 | 16.00 |
| Rosin K-O                                | 280 lb.  | 16.00 | 17.00 |
| Rosin W-X                                | 280 lb.  | 17.00 | 17.50 |
| Spirits of turpentine                    | gal.     | 73    | —     |
| Wood turpentine, steam distilled         | gal.     | 62    | 65    |
| Wood turpentine, destructively distilled | gal.     | 58    | —     |
| Fitch                                    | 200 bbl. | 8.00  | —     |
| Tar, kiln dried                          | 280 lb.  | 13.00 | 13.50 |
| Retort tar                               | 280 lb.  | 14.00 | 14.50 |
| Rosin oil, first run                     | gal.     | 80    | —     |
| Second run                               | gal.     | 83    | —     |
| Third run                                | gal.     | 88    | —     |
| Fourth run                               | gal.     | 98    | —     |

### Vegetable Oils

|                          |      |        |        |
|--------------------------|------|--------|--------|
| Castor oil               | lb.  | 34     | 38     |
| China wood oil           | lb.  | 27     | 28     |
| Cocoonut oil             | lb.  | 16 1/2 | 22     |
| Corn oil                 | lb.  | 18     | —      |
| Cottonseed oil, crude    | lb.  | 20     | 22     |
| Lined oil, raw, cars     | gal. | 1.81   | 1.86   |
| Olive oil                | gal. | 4.25   | 4.50   |
| Peanut oil, crude        | lb.  | 18     | 22     |
| Soya bean oil, Manchuria | lb.  | 17     | 18 1/2 |

### Glues

|                            |      |      |      |
|----------------------------|------|------|------|
| Extra white                | lb.  | 36   | 45   |
| Cabinet                    | lb.  | 31   | 40   |
| Brown foot stock           | lb.  | 18   | 22   |
| Fish glue, 50-gal. barrels | gal. | 1.00 | 1.80 |

### Miscellaneous Materials

# INDUSTRIAL

Financial, Construction and Manufacturers' News

## Construction and Operation

### Alabama

**CHOCTAW POINT**—The Consumers Dry Woods Products Co., Mobile, will increase the capacity of its plant.

### Arizona

**FLAGSTAFF**—The Navajo Copper Co. will build a leaching plant having a daily capacity of 100 tons. G. A. McCollough, manager.

**KINGMAN**—The Industrial Finance Co., 50 East 42nd St., New York City, N. Y., will build a 40 x 140 ft. plant for the production of fiber and fiber products from the Yucca plant.

**PATAGONIA**—The Mowry Mining Co. will build a new concentration plant at its local mining properties.

**TUCSON**—The Pima County Smelting Co. will build a large reduction plant to provide for increased operations. Address C. M. Garrison.

### Arkansas

**BATESVILLE**—Dr. Tooker will build a manganese washing plant here and is in the market for a log washer, belts, power, jig irons, pulleys and shafting.

### California

**COVINA**—The city has awarded the contract for the installation of a chlorination plant at the intake of the city reservoir supplying water for domestic use, to the California Jewell Filter Co. Estimated cost, \$8,000.

**MARE ISLAND**—The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans to build an oxy-acetylene generating plant, under Specification No. 3522, noted Oct. 15.

**MARTINEZ**—The Shell Oil Co. will build an addition to its refinery. Estimated cost, \$80,000.

**MELROSE** (Oakland P. O.)—The National Lead Co. will build several reinforced-concrete factory buildings here. Estimated cost, \$300,000. H. A. Broberg, 485 California St., San Francisco, is preparing plans, \$25,391.

**SAN DIEGO**—L. M. Cox, Commandant, 12th Naval District, has awarded the contract for the construction of seven air school buildings, on North Island, to the Los Angeles Planning Mill Co., 1812 Industrial St., Los Angeles. Project includes the construction of laboratories, oil storage and reclaiming buildings, etc. Total estimated cost, \$50,000.

**SAN FRANCISCO**—The Bureau of Foreign and Domestic Commerce, 307 Custom House, has information regarding a firm in Russia which is in the market for complete equipment for a sulphate-cellulose mill and a paper factory. Refer to file No. 20200.

### Colorado

**LEADVILLE**—The Fanny Rawlings Mining Co. will rebuild its surface plant recently destroyed by fire, entailing a loss of \$13,000. W. C. Frost, superintendent.

### Connecticut

**PLAINVILLE**—The Trumbull Electric Manufacturing Co., Woodward Ave., has awarded the contract for the construction of a sewage disposal plant to A. D. Marco, Southington. Estimated cost, \$10,000. Noted Nov. 15.

### Delaware

**WILMINGTON**—The E. I. du Pont de Nemours Co. will build a two-story plant 45 x 50 ft. addition to its local organic laboratory. Estimated cost, \$25,000.

### Kansas

**TREECE**—Col. & Matthews, Picher, Okla., will remove its plant from Picher to

Treece and remodel same. The company is in the market for roofing, cement, mill hardware, pipe, pump, sludge tanks, bolts, concrete and lumber. Estimated cost, \$40,000. J. H. Kleinfelter, superintendent.

### Maryland

**BALTIMORE**—The United States Emergency Fleet Corporation, Housing Department, 253 Broad St., Philadelphia, Penn., will build a sewage disposal plant here. Estimated cost, \$50,000. Norton, Bird & Whitman, Munsey Building, engineers.

### Massachusetts

**HINGHAM**—The Bureau of Yards and Docks, Navy Department, Washington, D. C., will build a TNT plant here. Estimated cost, \$150,000.

### Michigan

**DETROIT**—The Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of a factory building; acid plant here. Estimated cost, \$150,000.

**DETROIT**—The Cummings & Moore Graphite Co., 672 Water St., has awarded the following contracts for the construction of a factory building; carpentry, to David J. Osgood, 220 West Elizabeth St.; masonry, to Stokes & Whittingham, Penobscot Building. Noted Oct. 31.

### Minnesota

**WORTHINGTON**—The State Board of Control will build a filter plant having a capacity of 80,000 gal. and a pumping plant; filter equipment will be installed in same. D. F. Mullen, secretary. L. P. Wolfe, 1000 Guardian Life Building, St. Paul, engineers.

### Missouri

**JOPLIN**—The Badger Mining Co. has awarded the contract for the construction of a concentration plant, to Edgar Foster. Estimated cost, \$56,000.

**JOPLIN**—The Freehold Oil & Gas Co. has taken over two leaseholds in the Waco-Lawton field, and will build a 200-ton mill on each tract. W. S. Marquiss, Weh Chy, manager.

**KANSAS CITY**—The Jensen-Salsberry Laboratories, 1320 Main St., will build a three-story, 56 x 120 ft. rein.-forced concrete and brick laboratory. Estimated cost, \$65,000. E. O. Brostrom, 212 Leeward Building, architect. Noted June 20.

### New Jersey

**CAPE MAY**—The Bureau of Yards and Docks, Navy Dept., Washington, D. C., will receive bids until Nov. 15 for the construction of a blacksmith, coppersmith and electric shop. Specification No. 3051. Estimated cost, \$20,000.

**CLAREMONT**—The Standard Oil Co., 26 Broadway, New York City, will build a reinforced-concrete filter and tank house at its Eagle works here.

**NEW JERSEY CITY**—The Davis-Bournonville Co., Van Wagon Ave., manufacturer of acetylene goods, will build an addition to its plant. Estimated cost, \$75,000.

**NEW JERSEY CITY**—The Van Dyke Chemical Co., 57 Wilkison Ave., will rebuild its plant recently destroyed by fire entailing a loss of \$10,000.

**NEWARK**—The Butterworth-Judson Corporation, Avenue R, will install a large quantity of new nitrating equipment to replace the chemical stoneware now in use.

**NEWARK**—The Oxwell Acetylene Co., 410 Frelinghuysen Ave., has awarded the contract for the construction of a three-story, 42 x 100 ft. factory addition to Fred K. Reus, 1320 6th St. Estimated cost, \$19,500. Noted Oct. 31.

### New York

**BROOKLYN**—McGosson & Robins, 91 Fulton St., New York City, will build a two-story, 60 x 80 ft. factory addition for the manufacture of drugs on North 11th and Perry St. Estimated cost, \$35,000. T. Engelhardt, 305 Broadway, architect.

**BROOKLYN**—The Ohio City Oil Co., Varick Ave., has awarded the contract for the construction of alterations to its plant, to the William Kennedy Construction Co., Montague St. Estimated cost, \$10,000.

**BROOKLYN**—The Standard Oil Co., 26 Broadway, New York City, has awarded the contract for the construction of an addition to its plant at the Gowanus Canal and 2nd St., to the H. W. Smith Contracting Co., 385 Lexington Ave., New York City. Estimated cost, \$25,000.

**BUFFALO**—The Aluminum Castings Co., 2800 Harvard Ave., Cleveland, Ohio, has awarded the contract for the construction of a three-story laboratory at 1850 Elmwood Ave., to the Schaaf Construction Co., Buffalo. Estimated cost, \$20,000. Noted Nov. 15.

**BUFFALO**—The Donner Steel Co., 375 Abbott Road, will build a concrete and steel laboratory and engineering office. Estimated cost, \$35,000.

**BUFFALO**—The Prest-O-Lite Co., 266 Amsterdam Ave., New York City, has awarded the contract for the construction of a plant which consists of 4 units, to John W. Cowper, Constable Building. Estimated cost, \$100,000.

**NEW YORK**—The John Trager Steam & Copper Works, 447 West 26th St., has awarded the contract for the construction of a four-story concrete and brick factory, to Garret S. Wright, 415 West 24th St. Estimated cost, \$20,000.

**OTISVILLE**—The Construction Division of the War Department, Washington, D. C., will build an addition to its present laboratory in connection with the additional hospital facilities at the Tuberculosis Hospital here. Total estimated cost, \$312,573.

**YAPHANK**—The Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of a sewage disposal plant here, to the Beaver Engineering & Contracting Co., 51 Chambers St., New York City.

### North Carolina

**ANDREWS**—The Andrews Tanning Co., Lock Haven, Penn., recently organized with \$50,000 capital, will build an extract plant here.

### Ohio

**AKRON**—The Commissioners of Summit County received bids for the construction of a sewage disposal plant for Summit Co. Infirmary buildings, from Kovel, Walsh Construction Co., Akron, \$12,768; Herman House, Akron, \$15,102. D. Dovers, Akron, \$15,468. M. P. Laufer, 425 Ohio Building, engineer. Noted Oct. 31.

**ANCHOR**—The United States Government has awarded the contract for the construction of a nitrate plant at here, to the George A. Fuller Co., Swetland Building, Cleveland.

**ANCHOR**—The Air Nitrates Corporation, 360 Madison Ave., New York City, N. Y., will build the first unit of its new plant here. Estimated cost, \$20,000, the output to be used for government service exclusively.

**CLEVELAND**—The Grasselli Chemical Co., Guardian Building, will rebuild its two-story, 60 x 120 ft. factory, which was recently destroyed by fire. Estimated cost, \$50,000.

**CLEVELAND**—The Ohio Chemical Co., 1177 Marquette Road, will build a factory on a site it recently purchased. J. H. Shales, secretary.

**CLEVELAND**—The Ohio Metal Braketting Co., 909 Schofield Building, will build a one-story, 54 x 102 ft. factory. Estimated cost, \$50,000. Frank Smith, c/o owner, architect.

**WILLOUGHBY**—The Construction Division of the War Department, Washington, D. C., will build a medical building and additional barracks, etc., here, for the use of the Chemical Warfare Service. Total estimated cost, \$167,670.

### Oklahoma

**MIAMI**—The Ron-Ani Mining Co. will build a 150-ton concentration plant and is in the market for sludge and slime tables, crushers, rollers, hollers, wire mesh, drills, engine, air compressors, lumber, roofing and holsts. Estimated cost, \$50,000.

**MIAMI**—The Greenback Mining Co. will build a 200-ton concentration plant and is in the market for motors, electric wiring, sludge and slime tables, crushers, air compressors, conveyors, roofing, lumber, engine, jess, hollers, rollers and wire mesh. Estimated cost, \$50,000. T. C. Greenback, superintendent.

**ST. LOUIS.**—The Lucky Strike Mining Co., Miami, will rebuild its concentration plant recently destroyed by fire and is in the market for mill hardware, mill roofing, lumber, concrete, sludge and slime tables, engine, boilers, pipe, crushers, air compressors, conveyors, belt drives, ore cars, ore cars and track. Estimated cost, \$65,000. E. H. Austin, superintendent.

**TULSA.**—The City Commissioners will install an additional filtration plant and add sufficient facilities to handle from 6,000,000 to 7,000,000 gal. water daily.

## Pennsylvania

**FRANKLIN.**—The Franklin Quality Refining Co., Lambertson Bank Building, will build a new filter house at its local refinery. Estimated cost, \$100,000.

**MARIETTA.**—The Gilliland Laboratories Co. will rebuild its plant here recently damaged by fire.

**NOXEN.**—The Noxen-Armour Leather Co., Union Stock Yards, Chicago, Ill., has awarded the contract for the reconstruction of a two-story concrete and brick tanning plant to Westinghouse, Church, Kerr & Co., 37 Wall St., New York City, N. Y. Estimated cost, \$500,000.

**PHILADELPHIA.**—The Keystone Lubricating Co., 21st and Clearfield St., will build a 20 x 225 ft. plant to its plant for the manufacture of grease.

**SHARON.**—The Sharon Steel Hoop Co., South Irving Ave., will build two additional open hearth furnaces, a by-product coke plant and possibly another blast furnace.

**SWEDENLAND.**—The Rainey-Wood Coke Co. formed by the Allen Wood Iron & Steel Co. and the W. J. Rainey Estate of 52 Vandenberg Ave., New York City, N. Y., will build a byproduct coke oven plant to produce 1200 tons of coke daily for use in blast furnaces and large quantities of ammonium sulphate and other chemicals.

## Texas

**BURKBURNETT.**—D. B. Welty, Cushing, Okla., and associates, will build an oil refinery here having a daily capacity of 2000 barrels, upon site recently purchased.

## Utah

**SALT LAKE CITY.**—The Vipont Mining Co. will build a 250-ton concentration plant in the Ashbrook District of Boxelder County. C. A. Phillips, president.

## Virginia

**NORFOLK.**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will soon award the contract for the construction of an acetylene generating plant, oxy-acetylene and generating plant here. Estimated cost, \$110,000. Noted Oct. 31.

**RICHMOND.**—The Southern Oil Products Co., recently incorporated with \$50,000 capital, will establish a local plant and is in the market for machinery and equipment for the manufacture of oil specialties. The initial installation is estimated to cost \$10,000. W. H. Warren, 761 American National Bank Building, president.

## Washington

**PUGET SOUND.**—The Bureau of Supplies & Accounts, Navy Department, Washington, D. C., has issued bids for the construction of acetylene and oxy-hydrogen generating plant, Schedule No. 1553, Class 11, from Alexander Milburn Co., Baltimore, Md., \$900 (part bid); Burdett Manufacturing Co., 209 St. John St., Chicago, Ill., \$38,892; Davis Bourneville Co., Van Wagon Ave., Jersey City, N. J., \$42,128, alternate, \$38,897; International Oxygen Co., 115 Broadway, New York City, N. Y., \$44,117, alternate, \$53,175.

## West Virginia

**CHARLESTON.**—The West Virginia Water & Electric Co., 131 Summers St., has awarded the contract for remodeling and building additions to its existing plant, to the Charleston Concrete Construction Co., Charleston.

**MARTINSBURG.**—The National Shale Brick Co., recently incorporated with \$250,000 capital stock, will build three brick plants. Address H. H. Emmert, Martinsburg.

**WATSON.**—The State Board of Control, Clarksburg, will build a sewage-disposal plant here.

## Wisconsin

**MARINETTE.**—The Marinette-Menominee Paper & Pulp Co. has awarded the contract for the construction of a sulphite mill and two towers, to the Northern Boiler & Structural Co., Appleton.

**MILWAUKEE.**—The Modern Steel Treating Co., 223 Beecher St., will rebuild its plant recently destroyed by fire, entailing a loss of \$20,000.

**WAUWATOSA.**—The Northwestern Chemical Co., 61st and State St., has awarded the contract for the construction of a one-story, 48 x 147 ft. chemical plant, to C. A. Kleppe, 1026 1st St., Milwaukee. Estimated cost, \$20,000. Noted Oct. 15.

## Wyoming

**BIG SANDY.**—The Producers & Refiners Corporation, 101 California Building, Denver, Colo., will build a casing-head gasoline plant, having a daily capacity of 10,000,000 cu ft. on their property in the Big Sand Draw Field. T. G. Smith, of the International Trust Co., and California St., Denver, Colo., director.

## British Columbia

**GRAVES POINT.**—The Granby Consolidated Mining, Smelting & Power Co., 718 Groulx St., Vancouver, will build a by-product plant. Estimated cost, \$1,250,000.

**IOCO.**—The Imperial Oil Co. Ltd., Cambie and Smythe Sts., Vancouver, will build an addition to its oil refineries. Estimated cost, \$250,000. J. E. Sirdwan, superintendent.

**VANCOUVER.**—The Drum Lummon Copper Mines, Ltd., 115 Dominion Building, will install a Gibson mill and concentrator in its works at Drum Lummon Bay, Douglas Channel, to have a daily capacity of 36 tons. Estimated cost, \$5,000.

## Ontario

**TORONTO.**—The Palmolive Co. of Canada, 64 Natalie St., will build an addition to its plant. Estimated cost, \$10,000.

**WINDSOR.**—The British American Oil Co., Royal Bank Building, Toronto, will build a concrete and steel distributing plant. Estimated cost, \$150,000. T. S. Merrill, 25 Woodland St., Detroit, Mich., secretary.

## Industrial Notes

THE UNITED FILTERS CORPORATION, of Brooklyn, N. Y., have found it necessary to move to larger quarters. The Eastern works testing laboratory will be in its own building at 355 Cortlandt Street, Bellevue, N. Y., and the sales office is now located at 65 Broadway, New York City.

RICKETTS & Co., Inc., New York City, formerly of 80 Maiden Lane, announce that, in order to meet increasing business requirements they have found it necessary to move to larger offices at 280 Madison Ave. By associating with them Charles E. Wagstaffe Bateson, and Dr. M. L. Hamilton, and by securing the services of T. A. Shegog, formerly assistant professor of chemistry and metallurgy for the county of Monmouth, they have placed themselves in a position not only to carry on their mining and metallurgical consulting business on an enlarged scale, but also to handle the most varied organic and inorganic manufacturing problems and related chemical work. Small samples for assay or analysis should be placed in parcels post to the office, large samples by express to the laboratories, 7 Dutch Street, New York City.

THE LOCOMOTIVE PULVERIZED FUEL CO. has just received an order from Morris & Co., Chicago, Ill., for equipping its steam power plant at Oklahoma City, Okla., with a complete "Lopulco" system for crushing, drying, pulverizing and burning coal. Native coals are expected to be used in conjunction with Texas lignite. The power plant contains seven Edgemoor boilers, having a total of 3100 horsepower, all of which are to be equipped with the "Lopulco" system.

THE BARBER-GREENE Co. announces the strengthening of its organization as follows: F. E. Smith, chief engineer, formerly of the engineering department of the Stephens-Adams Mfg. Co., of the Granby Mining & Smelting Co., and the American Zinc & Chemical Co., Geo. C. Sanford, superintendent, formerly of the Elevator Supply Co., and of the Otis Elevator Co.

THE FEDERAL DYESTUFF & CHEMICAL CORPORATION OF KINGSPORT, Tenn., has decided to call itself the Union Dyestuff & Chemical Corporation.

## Manufacturers' Catalogs

THE W. S. ROCKWELL Co., 50 Church Street, New York, calls attention to two new bulletins. Bulletin 36 illustrates and describes filtering reverberatory melting furnaces for non-ferrous metals in capacities ranging from 500 to 2000 pounds. Bulletin 37 illustrates a type of furnace used for heating, purifying, and casting copper and similar products, without oxidation. Figs. 1 and 2 illustrate equipment in an Eastern wire mill; Figs. 3 and 4, an installation at a big copper mining company in Montana. Fig. 5, with the table attached, shows that it is self-explanatory. This installation was made in the West and while the results secured were very good, still it is expected that they will be greater, better, when the operators become more familiar with the furnace. Copies will be sent to any one who can use them to advantage.

THE PACIFIC TANK & PIPE CO., San Francisco, Calif.: A very attractive 123-page booklet, Catalog No. 12, illustrates and describes the latest improvements and ideas in cyanide plant equipment. Standard dimensions, capacities and weights of tanks which this company can furnish are given, together with the list price of each.

THE SOWERS MANUFACTURING COMPANY, Buffalo, N. Y.: Catalog IV covers the Dopp line of copper, nickel, and steam jacketed kettles, mixers, and vacuum pans, which are described and illustrated.

THE J. P. DEVINE Co., Buffalo, N. Y., has just received from the press three bulletins. Bulletin No. 101 illustrates and describes the patented Devine patented vacuum chamber dryers. Bulletin No. 106 deals with single and multiple effect vacuum evaporators, vacuum pans, distilled water, and vacuum pans. Bulletin No. 107 is on high efficiency vacuum pumps, both rotary and slide valve type. In these bulletins the illustrations are photographs showing actual installation of apparatus. Copies of these bulletins will be gladly sent to anyone interested in the types of apparatus described.

THE HANOVIA CHEMICAL & MFG. CO., Newark, N. J.: Announced a new bulletin, No. 20W, descriptive of the Hanovia Quartz Lamp, a scientifically designed and efficiently practical source of the ultraviolet rays, which are being successfully used in the chemical industry. The bulletin contains facts regarding some of the uses for the lamp and its adaptability.

## New Publications

TESTS TO DETERMINE THE RIGIDITY OF RIVETED JOINTS OF STEEL STRUCTURES: Bulletin 104, issued by the Engineering Experiment Station of the University of Illinois, Urbana, Ill.

MAXIMUM BITUMINOUS COAL PRICES, F. O. B. AT THE MINES. Publication No. 4E, published by the United States Fuel Administration, Washington, D. C. These prices were in effect Oct. 7, 1918.

NEW UNITED STATES GEOLOGICAL SURVEY PUBLICATIONS: 1.7, Tin in 1917, by Adolph Knopf; Mineral Resources of the U. S., 1917, Part I (pages 63-72), published Sept. 16, 1918; 1.8, Silver, Copper Lead and Zinc in the Central States in 1917, Mines Report, by J. P. Dunlop and B. S. Butler; Mineral Resources of the U. S., 1917, Part I (pages 73-120), published Oct. 24, 1918; 1.13, Fuller's Earth in 1917, by Jefferson Middleton; Mineral Resources of the U. S., 1917, Part II, (pages 253-255), published Sept. 18, 1918; 1.14, Coal in the Central States in 1917, by James M. Hill; Mineral Resources of the U. S., 1917, Part II, (pages 255-291), published Oct. 14, 1918; Bulletin 104, The Manufacture of Retort Coal-Gas in the Central States, Using Low-Sulphur Coal from Illinois, Indiana and Western Kentucky, by W. D. Perkins and W. W. Odell, is published by the State of Illinois, Dept. of Registration and Education, Division of the State Geological Survey, Urbana, Ill.

NEW BUREAU OF MINES PUBLICATIONS: Tech. Paper 139, Low-Rate Combustion in Fuel Beds of Hand Fired Furnace. By Henry Kreisinger, C. E. Augustine and S. H. Karp, Tech. Paper 136, Methods for the Determination of the Explosive Properties of Routine Work of the Bureau of Mines. By S. P. Howell and J. E. Tiffany; Tech. Paper 132, Production of Explosives in the United States During the War, 1914-1917, with notes on coal-mine accidents due to explosives and list of permissible explosives tested prior to April 30, 1918. Compiled by Albert H. Karp, Tech. Paper 131, The Tars Distilled from Bituminous Coal in Hand-Fired Furnaces. By S. H. Katz.

### The Reconstruction Conference To Be Held at Atlantic City

IN our last issue we called attention to the War Emergency and Reconstruction Conference to be held at Atlantic City on Dec. 4, 5 and 6. Now we urge our readers who are engaged in industries affected by the war to put in appearance if possible. It is a meeting of the 380 or more War Service Committees and the Chamber of Commerce of the United States, under the auspices of which it is called. These various committees have been consolidated into thirty-five groups which foregather separately on Dec. 4. Then they are merged into ten major groups which meet separately on Dec. 5 and in conclusion they come together for final action on Dec. 6. In the meantime a number of general sessions will be held in the Great Hall of the Million Dollar Pier at which eminent speakers will be present and make addresses. They will be open to the public.

A questionnaire containing twenty-five leading queries has been sent out by Mr. W. H. MANSS, director of the War Service Executive Committee, to all members of the War Service Committees. These cover a wide field and relate to definite problems such as unfilled orders for war materials, skilled and unskilled labor, financing, methods of canceling war orders, disposition of war materials, the continuation of the War Industries Board, control of materials during reconstruction, demand for finished products under peace conditions, raw materials, cost accounting, conservation, elimination of unnecessary products and wasteful practices, the requirements for the rehabilitation of allied countries and what we can supply until they are rehabilitated, the merchant marine, foreign competition, the Webb-Pomerene bill, etc.

The urgent need of careful and constructive thought on these and other matters is too evident to call for discussion, because legislation is certain, and if the leaders of industry do not agree upon plans we shall have to meet laws that are made without plans. With no disrespect toward Congress, we know that most of its members are lawyers, that very few of them are men of industrial experience, that sound economists are rare among them, that all must of necessity engage in politics, that politics addresses itself to what is called window-dressing—that is, to making the measures supported appeal to the popular fancy—and that industry has an entirely different task, which is to furnish the goods.

It is necessary, therefore, that whatever legislation is proposed be offered with good reason and that undue advantage for any industry shall not be sought at the expense of the general welfare. If it is, legislators

should not support it, and the best of them will not. On the other hand, if the measures proposed be conceived in a broad, patriotic spirit, with the general welfare of the people constantly in view, then politicians will vie with one another in coming to their support.

Many problems other than those involving legislation are to be considered, as those mentioned indicate. We cannot let them lie, thinking they will take care of themselves. If we do not look after them they will run away from us, and leave us stranded.

## A Grinding Problem

### That Crushed an Editor

LUTHER W. LENNOX contributed a very noteworthy paper to the Colorado meeting of the American Institute of Mining Engineers on the "Crushing Resistance of Various Ores," giving his method of obtaining a number which represents the relative difficulty in grinding rock. This factor is evidently so useful in the solution of various problems in reducing mill feed that the author received many well-deserved compliments on his neat and simple method.

One member pointed out, however, that the title was rather illy chosen, since the method compares the work necessary to reduce a 10-mesh feed, which operation the mill-man terms "grinding," reserving the word "crushing" to denote the operation of breaking mine-run to granules. Considerable merriment was provoked by Mr. Lennox's rejoinder that his original manuscript used the word "grinding" exclusively, but that the editor saw fit to change this word to "crushing" in each instance, despite his protest.

A conscientious editor naturally wonders how directly this pointed expression of disapproval applies to his own work. Men occupying the high literary places have so often expressed their disgust with the inelegant spoken and written language of the average American engineer that the technical man has almost come to accept their words at their face value. Very true, few engineers can write with Macaulay's clarity, Stevenson's absorbing interest, or Clemens' wit; but, indeed, where is the editor who can? And there is a lurking suspicion in the mind of the man on the job that the farther up in the clouds of literary expression the writer flies, the poorer his vision of the ordinary details of making the enterprise earn dividends!

Perhaps we editors are fussing too much over nomenclature; too much horrified at the split infinitive; insisting too strongly on our individual predilections for those intangible elements of "style." The other fellow's style may be as good as ours—a shiny boot, while correct for city wear, is a poor working shoe. When we rub elbows with the busy successful engineer with a coveted store of knowledge, our sins are visited on our own heads when he declines to put it on paper "because he can't write." Ten to one, if he would only dictate his thoughts to a stenographer in the abandoned way he would word a business letter, we would find so much meat in the effort that we would gladly thresh it into shape and put the finishing literary "polish" on it without which it would not pass acceptance, even though it might add only a little to the intrinsic merit of the contribution.

## Engineers Needed for Engineering Faculties

PERHAPS Dr. MANN's report on engineering education, recently published by the associated societies which instituted the investigation, will indicate to those responsible for our technical curricula the tremendous gap between those offered by them and those required by prospective engineers. Practicing engineers, at least, are keenly aware of the deficiencies in their own education and of those whom they employ, since early in the investigation an inclusive questionnaire brought out the fact that in their judgment the factors most important for success were of the following importance and rank: Character, judgment, efficiency, understanding of men, knowledge and technique. Speaking generally, it is unquestionable that our schools are spending the bulk of their effort on giving their students a kaleidoscopic acquaintance with engineering science and technique to the substantial exclusion of the four other vastly more important qualifications.

Engineering education is broadly defined by Dr. MANN as a means by which production can be increased. In order to improve engineering education in this sense, three things are needed: First, better students; second, better curricula; and third and doubtless most important, better instructors. The 60 per cent mortality among the student body is adequate proof that the admission requirements are fundamentally wrong—many pupils are passed through high schools to rid them of an overwhelming burden of ignorance. Too many of these boys and girls then enter higher institutions on the strength of their poorly earned standing, or by an examination which tests their ability to "cram." Little thought and effort are given to determine whether the man has the willingness and capacity, the moral and physical stamina to go the hard road leading to real achievement. Those lacking physical stamina and technique may infallibly be eliminated by observing a probationary performance at some laborious shop-work, but tests for capacity, ability and character are still being sought. It will take better faculties to find them and, after finding them, to apply them.

Better curricula are urgently needed. The present style is congested beyond endurance, is too often an engineering potpie, with a half-baked foundation and indigestible crust. As Dr. MANN points out, a correct plan demands that the time schedule be determined by subject matter essential to the equipment of the engineer, instead of the present opposite practice. It will require broad-minded comprehension of the prospective needs of engineers to determine the subject matter essential to the equipment of all engineers—"the common core" of engineering education—and in addition the subject matter essential for a specialist. It will require better men in the faculties, men who have a knowledge of engineering as written in books, but more—a knowledge of engineering as written in works.

Individually, one can find instances where nearly all the problems of scientific curricula-making have been solved. The point yet to be established is coördination. Coördinate and motivate the industrial, laboratory, scientific and humanistic work into a whole, appealing to the student as really worth while! Train him in the ability to perceive relationships between the value of a thing and its cost, between the humdrum of

daily work-routine and the underlying laws of nature, the principles of science and the human factors! As so defined, one is tempted to make the assertion that proper coördination in engineering schools is absolutely non-existent. It will take instructors of the highest class to institute it.

It has been clearly pointed out that in order to profit from the result of the investigation on engineering education the faculties and governing boards must be in sympathy with the new point of view. Respect for departmental autonomy must in some manner be overcome, the inertia of faculty meetings must be reduced, coöperation and coördination between the various departments of instruction must be absolute. Here again rises the ever insistent demand for a broad-minded, capable, enthusiastic teaching body, throwing their whole soul into the training of young men—that best work man can do—without the incubus of seniority, precedent and poverty which now frightens off so many good men. The governing boards who hold the purse-strings can thus do yeoman service in hastening the dawn of a new and better education, by providing the funds for the most essential requisite—a better faculty.

### Labor and Machinery In Iron Industry

ONE clear result of the war is a great increase in labor costs in the iron and steel industry. Unless the cost of machinery and equipment varies precisely as the cost of labor there is, obviously, a change in the relation between the two. When the relation stands at a certain level there is a point to which the introduction of "labor saving machinery," to use the common phrase, is advantageous, and beyond which it should not go. Every one recognizes, of course, that the "cost" of the machinery or whatever the equipment may be, when considered in this sense, is not the price that one pays for it, the cost in the abstract sense being a complex item involving first cost, current rate of interest on capital and whether or not a still better device may be developed within a short time.

There is good reason to believe that the changes that have been brought about by the war are such that the relation between the cost of labor and the cost of labor saving equipment has been altered to the disadvantage of employing labor and the advantage of employing machinery in the iron and steel industry. If so, there lies before the iron and steel industry an important period of improvement in the direction of displacing labor by machinery.

Incidentally, there is a contributing factor of no small importance, and that is that the tonnage capacity of the industry has grown so greatly that for a time there will be little disposition to increase capacity. As all going concerns are continually seeking to improve their position the talent they have will naturally be turned to the matter of improving the methods by which they turn out their present tonnage. In the past two or three years the case has been different. The object has been to increase tonnage the easiest way.

It might be argued that when there is a general advance in wage rates or a general advance in the cost of living, it affects everything more or less alike, hence the balance between the cost of employing a man and the cost of installing equipment to dispense with his

services has not been altered. The increase in wage rates and cost of living, however, has not affected all alike. The iron and steel industry occupies a peculiar position. Its common labor has been recruited very largely from the ranks of the foreign born, in other words it has depended chiefly upon immigration. The American born do not gravitate greatly towards employment at blast furnaces, coke works and steel mills. As to immigration, the statistics are simple and easily remembered. It is recognized that the rate varies according to industrial activity. The year ended June 30, 1913, was a very active one at iron and steel plants. The following twelvemonth was one of sharply decreasing activity. The statistics of the two years are therefore quite indicative of normal before the war. They showed, for aliens and citizens, a net movement into the country averaging almost precisely 60,000 persons per month. For four years July 1, 1914, to June 30, 1918, this movement would have involved 2,880,000 persons. The actual was about 280,000. Thus a "deficit" accumulated of about 2,600,000. In July, 1918, there were very few arrivals and many departures, making a net loss in population of 33,193. The departures were probably chiefly of civilians going abroad for war work, it is true, but recent surveys in the industry have disclosed a widespread intention of workers to go abroad, to hunt up relatives with whom connection has been lost and to scrutinize industrial and living conditions in their native countries in the changed conditions they have been told the war is to produce. A Connellsville coke producer made a canvass of his workmen with the following result: 25 per cent. intended to stay on the job; 25 per cent. intended to make a trip abroad; 50 per cent. intended to go abroad and stay there. Of course the men will not all do what they say they intend to do, but something of that sort is undoubtedly going to occur, and there will not be much immigration to balance.

The position of the iron and steel industry is that its common labor is of one class, while the labor used in making the appliances it buys is largely of another class. The supply of the former is depleted more than the supply of the latter. The changes due to the war do not increase the cost of the machine as much as the cost of the man.

The average of all wages in the United States is likely to come down from the level existing at the close of the war, but common labor in the iron and steel industry is not likely to come down as much as the general average. There is even a possibility of the rate per hour increasing. Taking the standard rate at 42 cents an hour, the 12-hour man, with the "eight-hour basic day" is paid for 14 times this for 12 hours' work, so that the cost to the employer is 49 cents an hour. If the supply of men willing to work 10 or 12 hours a day becomes insufficient the answer is not to increase the hours of labor per man, but to make conditions such that additional men will be invited to seek the jobs. That may mean the introduction of the universal eight-hour shift, for as a rule the shift period must be a divisor of 24, and the wage rate may be higher than 42 cents an hour, or even 49 cents. It is certain that the ratio between iron and steel labor and labor in general has been increased, and that means that labor saving devices are worth more than formerly.

## The Glory Of the Peanut

Time was when we considered it a measure of distinction or importance for a person or thing to occupy space in the *Encyclopædia Britannica*; the more space, the greater the importance. The peanut is not mentioned in it. The *Standard Dictionary* gives an illustrated inch to it and announces that peanuts are beans on the ground that they are leguminosæ.

It is a lowly subject. On the railroad a peanut train consists of not more than two cars; as soon as the third is added the train becomes a "local." Those who engage in peanut politics are sometimes also referred to as small potatoes. Large potatoes have dignity, but no variety of peanuts achieves this rank either in literature or in colloquial speech. Nevertheless, these are days of democracy, and we demand that the world be made safe for it, so that the humble be made great. And just as some of our most cherished institutions such as monogamy, co-operative industry, the establishment of groups of states, paper-making and a thousand other manifestations of wisdom and ingenuity have been developed for us in insect, bird and other animal life of lower order than our own, so those things which we have scorned in days gone by are now achieving aristocracy in commerce and growing potentiality by leaps and bounds. Knick-knacks at five and ten cents each have built the tallest and handsomest office building in the world. The humble banana still retains its post on the street corner, now under Greek rather than Latin auspices, and since it has entered the portals of commerce as fruit, the ships to carry it have almost become the leaders of the tropic seas.

Holding its own along with the banana and still giving its name to the stands from which it is sold, the peanut abides, setting an example in literary culture which we have long been commending to the youth of our land; the more diligent study of Greek, with its vast wealth of literature, in the place of Latin. We offer the peanut in its shifting from Latin to Greek as a worthy exemplar to our authorities in education.

If sulphuric acid represents industrial advancement, why should not peanuts represent advancement in democracy? We mean true democracy, intelligent, cultured and constructive democracy, and not the anarchy of hate which we find among the Bolsheviks. They do not eat peanuts—and behold their madness and rage and destruction! The Germans developed their Kultur without the aid of peanuts, and they, too, have gone mad and the walls of their temple are falling in upon them and crushing them.

The peanut has always been striving to rise. We recall an estimable merchant, surely long since gathered to his fathers, who entered the Boston & Maine trains at Salem, Mass., many years ago, carrying a generous basket upon his arm and calling out, "Peanuts, peanuts; fresh roasted peanuts; five AND ten cents a bag." The ten-cent bags were triple the size of those sold for five cents. He was an honest merchant and gave good measure. It was only the buyer, however, or those seated near him who discovered the good man's desire to adjust his wares to the greatest measure of human consumption—and consequent betterment. We venture to suggest that this may have come from his association

with peanuts. A nod of the head or a raised finger brought him to attention and service, and as he lifted the cover of his basket he displayed three separate compartments. Then he would inquire, "Low, medium or high roast?" and whoever could not be satisfied with such peanuts was a churl indeed. We preferred the high roast, but that was a matter of taste. The dealer, who was a busy man and indisposed to enter into idle conversation, favored the low roast, owing to the superior quality of the nut he offered for sale. Despite the *Standard Dictionary*, he never referred to his wares as beans. And he certainly knew peanuts.

Early in the '90s we recall occasional negotiations with a corporation which was popularly described as the Peanut Trust. It flourished chiefly in Virginia, but extended its operations also into North Carolina. We do not know whether it still exists, and we mention it merely to show the peanut ambition, which is not a thing to be scorned. Everything important in the United States was being organized into some kind of a trust. Early in the game, peanuts were on hand—and organized.

Now observe the rise of the humble goober following the research of the good Sabatier and the scramble for patents to profit by his discovery. Before the war this country produced about three and a half million bushels annually. In 1916 production rose to 40,000,000 bushels. In 1917 we devoted 3,277,000 acres to its cultivation; and its crops are bountiful. This year Texas alone has 3,000,000 acres growing peanuts with the prospect of a bumper yield.

It has robbed the boll weevil of its injury, for the vine is hardy against it, and the farmer who erstwhile raised cotton only to see his fields destroyed now raises peanuts and buys Liberty bonds. It has shaken the foundations of the Temple of Scarcity which the hog built for itself, because its excellent oil, hardened into fat by hydrogenation, supplies humanity's need for butter and lard wherever ships can carry it. Thus, also, it eases the burden of the over-worked cow.

In addition to the peanuts that we grow and notwithstanding the difficulties and expense of shipping, our imports of peanut oil have increased six-fold since the war began and now reach over 8,000,000 gallons. If the Germans had offered Alsace and Lorraine back to France by way of honorable exchange, they could have received a generous portion of Northern Africa in return, and Northern Africa is a veritable paradise for peanuts. And the war might have been avoided because the Germans would have had their minds on something else. Then they would still be respected among men and every decent club and social organization would not be closed to them. Right here is where we see the subtle relation of peanuts to beans which is declared by the *Standard Dictionary*—a pretty good book, after all. The Germans didn't know beans in the large, true and catholic sense. They didn't know peanuts.

A new concept of measurement is added to human understanding. We have gaged the development of industry by statistics of sulphuric acid, of progress by steel and of civilization by soap. Now let us add the measure of democracy by peanuts.

## Readers' Views and Comments

### Measurement of Odors

*To the Editor Chemical & Metallurgical Engineering*

SIR:—The writers have read with much interest the letter of Mr. V. H. Gottschalk, which was published in the Nov. 15 issue of your esteemed journal, concerning our paper, "An Investigation of Stenches and Odors for Industrial Purposes," read at the Cleveland meeting of the American Chemical Society.

Evidently Mr. Gottschalk did not hear the paper read, and your reporter has been overly kind in crediting us with priority, which Mr. Gottschalk shows we have not deserved. No claims for priority in measurement of odors were made by us, although we were not aware of other work of the same nature; also we named our apparatus an "odorometer," and not "odometer," as Mr. Gottschalk prefers. These discrepancies are due to reportorial error which will be evident as soon as the paper itself appears. We have noted since this question has arisen that the Standard Dictionary defines the word "odorimeter."

It is gratifying to see the interest which our paper on this subject creates, and we are indebted to Mr. Gottschalk for bringing to our attention previous work which has been published. We agree that the subject is one which deserves much further study. For the present the data which we are publishing are all that are needed by the Bureau of Mines to serve its purposes. It may be that other work will be done at some future time, but for the present, at least, it is ended. For this reason we will turn the matter over to other investigators, hoping that the work will receive further impetus.

### Help for the Gold Producer

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—I have read with much interest your editorial of Nov. 1, "Help for the Gold Producer." I think the statement may safely be made that the currency situation is, next to the war, the most important problem that confronts the world. It is remarkable that the present state of unreality of our monetary standard is not more widely known and discussed than is the case. We are no longer on a gold basis, and, far worse, we are not even on any other definite, even if depreciated, basis. There is therefore nothing binding us to terra firma, and anything is possible with respect to inflation of prices. Already the stoppage of redemption of currency in gold and of international shipments of gold to adjust balances has resulted in expropriating from the widows and orphans et al. 20 per cent of their capital (American exchange is, or recently was, at about 20 per cent discount in countries still remaining on a real gold basis), but this is a small matter compared with what may happen yet.

As to the remedy, it is easy to say that all that is necessary is to get back to the gold basis. This, assuming it to be possible, would not remedy the rise in prices in so far as that is due to the depreciation in the value of gold—that is inevitable, although many

observers believe the pendulum is about to swing the other way—but it would get us back to earth again.

While we have cut loose from the gold basis so far as making payments in gold and gold-demand currency is concerned, we refuse to pay the gold producer more for his product than formerly; that is, he gets a dollar currency for a dollar gold. What else is possible? To do otherwise would be a contradiction in terms so long as gold remains, even nominally, the basis of currency. You justly observe that to pay a bounty would be equivalent to raising the price of gold, but it may be added that there is no way the price of gold could be raised except only by paying a bounty. To pay \$1 +  $x$  for \$1 gold (23.22 grains) would be a bounty, pure, simple and undefiled.

There is an apparent attractiveness about anything that will "raise the price of gold" because we have always understood that a rise in the price of gold is another way of saying a fall in commodity prices.

One thing stands out, namely, that there is a certain grim humor in any criticism of the gold producers for not being able to suggest a feasible way out of a situation which, as present legislation stands, presents the same difficulties as does lifting oneself by one's bootstraps. In saying present legislation I mean that immediate relief would be given the producers if they were allowed to ship their gold to Spain, for instance, and, with the proceeds of its sale, buy American exchange.

ERNEST A. LE SUEUR.

Ottawa, Ont.

### Analyzed Samples Wanted

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—We are building up a collection of analyzed samples of raw materials, intermediate and finished products of our typical chemical industries, and expect to use these specimens as practical material in our courses in quantitative and technical analysis.

It has been our experience that the work in analytical chemistry is greatly strengthened by the use of such material, but at present the time of most instructors is too occupied to devote the time necessary to make the analyses required to check the results of the students. The laboratories of many of our chemical manufacturers make such analyses as a matter of routine, and it would be a very helpful method of coöperation if they could turn over to use and to other universities laboratory samples together with their analytical data on the same. You have advocated a closer coöperation between the manufacturers and the universities and it appears to me that here is a chance for a definite service involving little extra work on the part of the works' laboratory forces. Samples of one to two pounds are sufficient for a year's supply, and different samples of the same material are useful in diversifying the work of different students of the same class. We shall be glad to pay transportation charges. The standard samples issued by the Bureau of Standards are too expensive for general use and their range is too limited. R. E. OESFPR.

## Western Chemical and Metallurgical Field

### Development of the Metallurgy of the Cripple Creek Ores

AMONG the many pleasant features of the recent Colorado meeting of the American Institute of Mining Engineers was a trip to Cripple Creek. The committee in charge followed the commendable plan of issuing a booklet describing briefly the notable features of the excursion, included in which was the following brief historical note on the metallurgy of sulpho-tellurides.

The first method adopted for local ore treatment, as has been the case in many other districts producing precious metal ores, was the stamp battery and plate amalgamation. During 1892 and 1893 ten stamp mills, with a total of 270 stamps, were erected. Although much of the gold from the surface ores occurred in a free state, it was soon proved that amalgamation was inefficient, due to the rusty nature of the gold. Concentrating tables and blankets were added to increase gold recovery, but even with these additions the extraction was low. Recovery became less and less as more of the unoxidized sulpho-tellurides were encountered, and stamp milling was soon entirely abandoned.

The first chlorination plant was built in the district by Edward Holden in 1893. Charles M. MacNeill was mill superintendent, and it was at this plant that D. C. Jackling secured his first position as assayer after walking into camp from Divide. From this time on various processes were tried for treating these ores, some fifteen mills in all being built. All of these were failures.

In 1895 a well-designed chlorination plant was built at Gillette under the supervision of J. Dawson Hawkins. This mill embodied all the improvements in chlorination known at that time. In 1897 the first cyanide mill (Brodie mill) was built at Mound City, under the direction of Philip Argall, following an earlier plant constructed in 1895 for the Metallic Extraction Co. at Florence. In 1896 and 1900 respectively Messrs. MacNeill, Penrose & Tutt built the Colorado & Philadelphia Chlorination Plant and the Standard Mill at Colorado City. Work was begun upon the Portland chlorination plant in 1901 and after operating as a chlorination plant for ten years following its opening in June, 1902, it was converted into a cyanide plant in 1912. In 1902 the Telluride Reduction Co. built a mill at Colorado City, employing bromine instead of chlorine; this was later converted into a cyanide plant, but finally failed in 1905. Philip Argall remodelled the plant, after it had been closed down for five years, into what is now known as the Golden Cycle Mill, and under the more recent management of A. L. Blomfield this has been developed into a highly efficient cyanide plant. Following the success of the chlorination mills built at Colorado City, the Union Chlorination Plant and the Dorcas Cyanide Mill were built at Florence.

From the first discoveries until recent years much of the ore produced in the Cripple Creek district has been shipped. After the first attempts at local milling, all of the higher-grade ore which was not smelted has been milled at plants located at Colorado City and Florence. Treatment of the ore outside the district continued un-

til the building of low-grade mills by Stratton's Independence, the Portland and the Vindicator companies. The development of successful processes for the local treatment of low-grade ore which could not stand the expense of shipment has been an achievement of the first order. This development has rendered profitable many of the waste dumps and large bodies of low-grade ore left standing in the mines, thereby greatly prolonging the life of the camp. Through persistent research and able business management the low-grade complex ores of the district are as efficiently treated as simpler precious metal ores occurring elsewhere. During 1907-8 a number of small plants were built for the cyanide leaching of coarsely crushed surface oxidized ores. The plants met with a greater or less degree of success, but at best were short lived on account of the limited quantities of ore available suitable for this treatment.

In 1908 Philip Argall erected and began operating the Independence Mill, using a combination of concentration and cyanidation. The same year, after extensive investigation, the Portland company erected the Victor Mill, which was placed in operation five months later than the Independence Mill. Shortly after the flotation process had proved successful upon various base metal ores in the United States the Portland company began investigation of the treatment of Cripple Creek ores by this method. After giving the process a thorough trial on a large scale it was finally abandoned in favor of the cyanidation, as formerly practiced. In 1916 the Vindicator company (the first to operate a flotation on a large scale in the district) built its present mill, which has since been continuously and profitably operated.

The chlorination process as practiced upon Cripple Creek ores was the barrel process as developed in the Black Hills from the crude barrel process used in South Carolina. Many improvements were made, and eventually it was operated upon a far larger scale than ever had been attempted in the Black Hills. For years there was a struggle for supremacy between the chlorination and the cyanide processes, each having very strong advocates. Up until the conversion of the Golden Cycle Mill to a cyanide plant the bulk of the higher-grade ores not shipped to smelters were treated by chlorination. Following the successful demonstration of the process at this plant, the Portland chlorination plant was converted to cyanide and the chlorination mills at Colorado City and Florence were closed. The two metallurgical developments which gave cyanidation the advantage were fine grinding and the introduction of efficient methods of slime treatment. It is of interest in passing to note that practically all the old chlorination tailing has been re-treated by the cyanide process at a profit. At present the Colorado Springs cyanide plant of the Portland company is closed, and this company is doing all of its milling at the mine, while the Golden Cycle Mill is the only mill now operating outside the district.

The cyanide process, as at present developed for the treatment of the higher-grade Cripple Creek ores, consists of coarse crushing in rolls or comminutors, followed by roasting in Edwards, Pierce-Turrett or Holthoff furnaces. After roasting, fine grinding is accomplished in either tube or Chilean mills. The product is either treated by straight agitation and filtration or, after separation of sand and slime, the sand is leached and the slime treated by agitation and filtration.

## Size vs. Recoveries in Ferromanganese Furnaces\*

BY E. S. BARDWELL

Metallurgist, Anaconda Copper Mining Co.

RECENT observation of a number of electric furnaces varying considerably in size and transformer capacity, and all working under the same conditions, shows the small furnaces to be much more efficient in operation than the large furnaces.

The furnaces examined were all of the same type. The crucibles consisted of tanks varying in size from  $7\frac{1}{2}$  x 15 ft. x  $4\frac{1}{2}$  ft. deep, to 12 x 20 ft. x 9 ft. deep, with linings formed of carbon electrode butts. The smaller furnaces had transformer capacity rated at 1500 kva.; the largest furnace had a transformer rated at 3000 kva. All of the furnaces were operated on 3-phase, 60-cycle current, the three electrodes being in a straight line. The voltages varied from 65 volts in the smaller to 100 volts in the larger furnaces. The charges consisted of manganese ore, coal, iron turnings and limestone in proper proportions.

The small furnaces, operating at low voltage, were making good recoveries. The slag loss was low and the volatilization loss almost nil. The larger furnaces, operating at higher voltages, showed increased loss of manganese in the slag and greatly increased volatilization loss when working on the same charges as the smaller furnaces or on charges similarly calculated.

The exact reasons for this state of affairs are difficult to state; a number of factors probably contribute to the results obtained in the large furnaces. First as to the effect of the higher voltage on manganese content of the slags. Increasing the voltage of the furnaces apparently tends to promote irregular working. The current takes the path of least resistance; this means superheating in certain areas in the crucible and insufficiently high temperatures in adjoining areas. The partially reduced manganese in the cooler areas passes into the slag and escapes further reduction.

As to the effect of the higher voltages on volatilization losses, it is clear that the result of the excessively high local temperatures will be to augment volatilization. Furnaces operating at the higher voltages are also subject to the formation of accretions consisting of carbide and graphite, which tend to form with an excess of carbon. The formation of carbide robs the charge of a portion of its lime, rendering the slag composition very different from that calculated and desired. The electrodes are forced up, and volatilization is still further increased. The presence of carbide and graphite in the furnaces working at the higher voltages points to the existence of higher temperatures in these furnaces than in those operating at lower temperatures. The small furnaces rarely show signs of accretions, although both carbide and graphite are formed in them to a limited extent.

The advantages to be gained from having a large unit are obvious, although there is much to be said in favor of a number of smaller units. Assuming for the moment that a large furnace is desired, let us consider the

voltage to be employed. It is evident that the large furnace possesses no advantage over the small furnace unless we can get proportional or more than proportional production from it. Output, of course, is dependent on power input. If we represent the current by  $I$ , the voltage between phases by  $E$ , and the reactance and impedance by  $X$  and  $Z$  respectively, we may write the following equations:

$$I = \frac{E}{\sqrt{X^2 + Z^2}}$$

$$Z = \sqrt{X^2 + R^2}$$

$$\text{Power input} = I^2 3 EI_p$$

where  $p$  is the power factor.

Examining the first equation, we see that the current input may be increased either by increasing  $E$  or by decreasing  $Z$ . Experiments have shown that in any given furnace the reactance,  $X$ , is a constant for all except the very lightest loads; hence any decrease in the resistance, according to the second equation, will result in a decrease in the impedance and a corresponding increase in the current and power input.

The resistance of the charge may be decreased by substituting coke for a part or for all of the coal. If this is done, and if the voltage be kept reasonably low, it should be possible to obtain increased power input and steadier operating conditions than are obtainable on the higher-voltage furnace.

R. Korten<sup>1</sup> gives some interesting data regarding the melting of ferromanganese in the electric furnace, particularly in the Keller furnace. He states that melting without loss of manganese by volatilization is most certain if low voltage is employed, that the arc must be short, and the hearth offer as large a surface as possible. A uniform heating over a large surface and not an intense heating over a small surface should be sought.

While conditions are not exactly the same in electric furnaces for the smelting of manganese ores, my experience has been that better results are obtained where low voltages are employed and when the power input is properly proportioned to the size of furnace employed.

When treating Montana carbonate ore containing 36.8 per cent Mn and 6.79 per cent  $\text{SiO}_2$ , using coal as reducing agent and marble as flux, it has been found possible to keep the slag loss below 3 per cent of the manganese in the ore. The average slag analysis over a period of a week was as follows: Mn, 4.26;  $\text{SiO}_2$ , 34.37;  $\text{Al}_2\text{O}_3$ , 7.93; CaO, 44.83; MgO, 4.10; BaO, 0.88 per cent.

This result is extremely good when compared with the slag losses quoted by Mr. Keeney, which vary from 12 to 25 per cent. Results like the former are easy to get in small furnaces working at low voltages. I feel confident that we shall be able to duplicate them in large furnaces after sufficient study.

The greatest problem yet to solve is the reduction of the volatilization losses. We know that it is possible to keep this loss low in the small furnaces, and doubtless a more thorough understanding of furnace conditions will enable us to solve the problem in the case of the larger units.

Great Falls, Mont.

\*Discussion of the paper of Robert M. Keeney, presented at the Colorado meeting, September, 1918.

## Atlantic City Meeting of War Service Committees

A WAR Emergency and Reconstruction Conference will be held at Atlantic City, N. J., during the week of Dec. 2, under the auspices of the Chamber of Commerce of the United States. Mr. Horace Bowker, president of the Chemical Alliance, Inc., will be chairman of Major Group No. 7, on Chemicals.

Preliminary conferences of the representatives of the 380 war service committees will be organized Monday and held Tuesday. Double sessions at 10 a.m. and 2.30 p.m. will be held at the Million Dollar Pier on Wednesday and Friday. Wednesday evening the 35 minor groups will meet at 8 o'clock. Thursday, at 10 a.m. a general session will be held, and at 2.30 and 8 p.m. the 10 major groups will meet separately.

### MAJOR GROUPS

1. Food Products
2. Heat, Light and Power
3. Iron and Steel
4. Metals and Minerals Other Than Iron and Steel
5. Textiles
6. Wood and Wood Products
7. Chemicals
8. Leather
9. Earthen Products
10. Industrial Professions.

### QUESTIONS TO BE DISCUSSED

1. What legal methods or means could be introduced in the craft to better stabilize prices, during the reconstruction period, affected by the following:

- a. Inventories on hand.
- b. Orders placed at war prices but not delivered.
- c. Labor costs and conditions.
- d. Increased taxes.
- e. Increased rates of interest.
- f. An estimated increased demand for non-war materials restricted during the war period.
- g. Will an increased production of your commodity increase the price of material or labor, or will a controlled redistribution of material and labor from war industries prevent such an increase?
- h. Discuss the practice of the sale of commodities at a price less than the cost of production. Its injury and disturbance on the industries and the ultimate consumer. What methods would you suggest to remedy this evil?
- i. If the Government sees fit to dispose of used materials and products in the open market, what effect will it have on your production and the sale of new goods? At home? Abroad?
- j. If it is not advisable for the Government to sell these goods on hand, either home or abroad, what shall it do with them?
- k. In this connection, what point of contact should business interests have with the governmental departments in the sale or disposition of these various commodities?

2. What is the estimated amount of labor, skilled and unskilled, male and female, required for the estimated 1919 production? What is to be the source of labor? How much must be moved? How much have you lost to war industries?

3. What is your financing problem during the reconstruction period? Do you recommend governmental aid? Is financial legislation needed? Should the Capital Issues Committee be continued during this period?

In this connection discuss and recommend what financial obligations, if any, the industries in your craft are under to the Government for moneys advanced for buildings, machinery or as loans or security for Government contracts. How are these to be liquidated or adjusted?

4. What method would you suggest for the cancellation of Government war orders with your craft that would create the least amount of hardship on the industries and permit a readjustment to normal commercial conditions?

5. On undelivered Government orders, what percentage of materials on hand, supplied either by the Government or purchased by you for these Government orders, can be utilized by your craft for commercial purposes during 1919? What disposition shall be made of those not usable?

6. Have you any suggestions to make as to the continuation

of the War Industries Board or any of its divisions, or any other governmental departments during the period of reconstruction? Such board or departments to have the authority to control materials and regulate prices. If so, for what period?

7. What intelligent control of materials during the reconstruction period could the War Service Committee suggest which would prevent an over or under supply and avoid a demoralization of the market? Should this be controlled by the crafts or by a governmental agency?

8. What effect had the war program on your output? Was it increased or decreased? Will there be an increased demand during the reconstruction period? If materials are uncontrolled will prices go up or down?

9. What is the estimated tonnage or unit of production of your raw materials for 1918? For 1919? Estimated demand for foreign commerce for 1919?

10. What is the estimated demand for your finished product for 1919? How does this compare with the average demand per annum in weight or unit of production for a five-year period immediately prior to 1914?

11. Sources of your raw materials? Domestic or imported? If domestic, can railroad cross-hauling be eliminated by purchasing nearer your plants? Causes of cross-hauling? If imported, at what ports? Would other ports of entry be more advantageous? What ports and why?

12. The value of a uniform method of cost accounting for the individual manufacturer and the craft as a whole.

13. What suggestions of the Conservation Division made to your craft might, with financial profit to your craft, be continued during the readjustment period? Is it possible to maintain a conservation schedule after the war, without legislative authority?

14. What methods and practices, other than those your craft has already introduced, would simplify production, save materials, eliminate wasteful practices, reduce the number of styles, without destroying individual creativeness?

15. What propaganda is necessary to educate the retailer and consumer to accept these eliminations and simplifications, and what plans might be arranged for better functioning with committees of jobbers and retailers handling your commodities?

16. What percentage of the commodities represented by your War Service Committee was produced in the United States before the war and what percentage imported? What suggestion have you to make for increased production for domestic and foreign commerce?

17. What effect will foreign competition have on your business? Will it increase or decrease your production?

18. What is the underlying reason for the importation of foreign-made goods: Prices? Styles? Label? Quality? Design? Or excess demand over domestic supply?

19. What disposition should be made by the Government of her merchant marine?

20. What steps have you taken, or do you propose to take, for the entire craft to take advantage of the Webb-Pomerene Bill, which allows combination for foreign trade, or have you other plans? What do you suggest as the best means of financing foreign credits? What percentage of the foreign commerce heretofore controlled by Germany can your craft obtain and supply?

21. What study is necessary, and what suggestions have you to make, in order to determine what are the needs of our allied countries for rehabilitation, and how far can you supply both raw and finished materials until they have been rehabilitated?

22. Has your craft been solicited by, or are you soliciting, foreign countries to supply these materials for rehabilitation purposes? If solicited, does this come from the Allies, or from neutral or enemy countries?

23. Would you recommend the appointment of a committee of United States manufacturers to confer with similar committees from our allies, to learn of their plans for protecting industry during the reconstruction period? Also to obtain information regarding commodities and supplies needed by them and ourselves during this period?

24. When the demobilization of military forces takes place, how can these men best be returned to their former industrial pursuits, and how will it affect your labor situation?

In this connection, how closely should the Conference work with the governmental bodies in the study of demobilization plans?

25. What suggestions have you to make to encourage and stimulate public work, such as the building of roads, pavements, water and sewer extension, the construction of public buildings, school houses, etc.? What effect will it have on the labor market?

In this connection consider the building program in the United States and especially the utilization or destruction of new plants built for war purposes. Location of convalescent and reconstruction hospitals near industrial centers so that these men can be trained in the factories nearest to the hospitals without creating new vocational schools.

System of Radio-active Elements

By INGO W. D. HACKB

TWENTY years ago saw the birth of a new science, the discovery of the radio-activity of thorium by G. C. Schmidt, Becquerel and Mme. Curie in 1898. Since that time we have witnessed a steady and gradual transformation in our conception of matter and new avenues have been opened for experimental investigation in many fields of physics, chemistry and biology. To-day we know of three series of radio-active substances, uranium, thorium and actinium series, which include about forty definite substances. Much work has been done to classify these forty radio-active substances and to establish their relationship to the periodic system of the chemical elements. Among the numerous publications on radio-activity and periodic system are those of van der Broek<sup>1</sup>, Cameron<sup>2</sup>, Meyer<sup>3</sup>, Russell<sup>4</sup>, Fajans<sup>5</sup>, Soddy<sup>6</sup>, Hönigschmidt<sup>7</sup>, Venable<sup>8</sup> and others. Thus the connection between the chemical elements and the radio-active substances is fairly well established. Investigations on the high-frequency spectra or X-ray spectra of the elements furnished the so-called atomic numbers of the elements, beginning with H 1 and ending with Uranium 92, thus giving us a continuous series of 92 elements (of which 5 elements are not yet discovered) with increasing atomic weight. The elements of atomic numbers 81 to 92, that is, those elements of highest atomic weights, show radio-activity, and the conclusion is, therefore, that the atom of such an element has become unstable and disintegrates, that is, breaks up by forming "elements," resp. isotopes, of lower atomic weight.

This integration or transmutation from an element of higher atomic weight to one of lower atomic weight takes place spontaneously at a definite period of time. This definite period is characteristic for each radio-active substance and is usually expressed in the "half-period," that is, the time required for the decay of one-half of any amount of a radio-active substance. This period is unchangeable and can at present not be affected by any physical and chemical means which our present knowledge offers. The disintegration takes place in two ways, according to two characteristic forms of transmutation, namely, the alpha-ray transmutation and the beta-ray transmutation.

The transmutation which is caused by the emission of alpha-rays lowers the atomic weight by 4 and the valency by 2 and makes the element more electro-positive. Alpha-rays are deviated by the magnetic and electric field and consist of positively charged nuclei of helium, traveling at a speed of about one-tenth the velocity of light and having a high power of ionization but small capacity of penetration, and are therefore quickly absorbed by the different media. They are of the type of the canal rays.

The transmutation caused by the emission of beta-rays makes the element more electro-negative, increases the valency by 1 and the atomic weight remains the same. Beta-rays are deviated by the magnetic field and consist of negatively charged electrons, having a speed of two-

THE HACKB PERIODIC SYSTEM WITH FLOW SHEET OF THE RADIO-ACTIVE ISOTONES

fifths to nine-tenths the velocity of light and possessing little power of ionization but high capacity of penetration. They are of the type of very fast cathode rays.

The gamma-rays are the secondary effect of the beta-rays, and can be compared with very hard X-rays, that is, they are produced by the impact of beta-rays (cathode rays) upon solids.

By the work of Ilievsky<sup>9</sup>, Fleck<sup>10</sup>, Metzner<sup>11</sup>, Fajans<sup>12</sup>, Klemensiewicz<sup>13</sup>, and others it has been found that the chemical nature of some radio-active disintegration products is similar to certain elements, and their experiments therefore confirm the evolution of the elements through the periodic table. Ordinary lead (atomic num-

ber 82) would, for example, consist of the following "isotopes":

|      |                  |                |
|------|------------------|----------------|
| PbRa | At. weight 206.2 | no radiation   |
| PbTh | At. weight 208.2 | no radiation   |
| PbAc | At. weight ?     | no radiation   |
| RaD  | At. weight 210.2 | beta-radiation |
| ThB  | At. weight 212.2 | beta-radiation |
| AcB  | At. weight ?     | beta-radiation |
| RaB  | At. weight 214.2 | beta-radiation |

and its atomic weight of 207.2 would be the average of the different isotopes and is dependent upon the period of these isotopes. In fact it has been shown by Mme. Curie<sup>1</sup>, Richards and Lambert<sup>2</sup> and others that the atomic weight of lead from different sources differs, and may range from 206.40 to 207.15, according to the minerals used.

In the lower part of the accompanying table, the different radio-active isotopes are placed under one another, while the radio-active disintegration is indicated by the arrows. It will be noticed that, with the exception of the first and last members of the uranium series, the disintegration of the three series follows the same course, and we have therefore triads of isotopes. The connection of the actinium series to the uranium series is not clearly established; lately Carruthers<sup>3</sup> and van den Broek<sup>4</sup>, by plotting certain radio-active constants, come to the conclusion that actinium should branch off from U, instead from U<sub>2</sub>, as shown in the table.

The periodic table as shown differs from the customary table in some respects. It enables a better classification of the elements into the three groups of non-metals, light metals and heavy metals. Each of these groups can be subdivided; for example, the "Light Metals" include group

1A—the alkali metals

2A—the earth-alkali metals

3A—the earth metals

while the carbon-group forms the transition points of these different groups. The table has been fully described elsewhere<sup>5</sup> and the connection of the elements with the isotopes can easily be seen.

The writer hopes that this table may serve not only as a better illustration of the disintegration of radio-active substances, but also as a clearer and more compact representation of the periodic system.

## Radium and Radio-activity

AT THE first regular meeting of the New Jersey Chemical Society, held at the Technical School in Newark, N. J., Nov. 11, 1918, Dr. Charles H. Viol presented an address on "Radium and Radio-activity." In discussing the modern conceptions of radio-activity, radiant energy, electrons, isotopes, atomic disintegration and the transmutation of metals, Dr. Viol said:

"To date there has been produced in the United States a total of nearly two ounces of radium in the form of finished material of high purity, and of this total one and one-third ounces (37 grams) have been produced in the Radium Research Laboratory of the Standard Chemical Co. of Pittsburgh. The U. S. Bureau of Mines has for a number of years been waging a propaganda which has been quite harmful to the development of the radium industry, the object being to make the production of radium a government monopoly, the argument in favor of this being that there is a total of not to exceed three and a half ounces of radium in the carnotite ore which can be mined in this country. Since this argument was first advanced (in 1914) most of the radium mentioned above has been produced, as it was only in January, 1913, that the first high purity radium was prepared in the United States, in the laboratories of the Standard Chemical Co. This company has since systematically developed its extensive carnotite holdings, and on the basis of findings the statement is fully justified that at least 20 ounces of radium can be prepared from Colorado carnotite. This flatly contradicts the estimates made by the employees of the Bureau of Mines and certainly weakens the arguments on governmental production of radium, or limitation of its use to therapy.

"The study of the phenomena of radio-activity, particularly the rays of the radio-elements and of the X-rays, has led to a clearer insight into the nature of the atom. According to Rutherford, the atom consists of a central positively charged nucleus surrounded by a ring or rings of negative electrons in rapid orbital motion. The nucleus is small in comparison with the dimension of the atom, and is made up of negative electrons with an excess of positive electrons. The positive electron is the hydrogen nucleus, which because of its smallness possesses a great electro-magnetic mass, 1700 times that of the negative electron. The hydrogen atom consists of a positive electron and one negative electron, which is in orbital motion about the nucleus. The helium nucleus consists of four hydrogen nuclei (positive electrons) and two negative electrons. The helium nucleus is remarkably stable, the experimental evidence indicating that the nucleus of the radio-element, when the atom transmutes, uses either a negative electron (beta ray) or a helium nucleus (alpha ray).

"In place of the old Periodic Law, we must now say that the chemical properties of the atoms are a periodic function of the nucleus charge. Isotopes are elements which have the same nucleus charge, but nuclei of different make up, consequently different atomic weights but identical chemical properties and spectra. Likewise two successive radio-elements which differ by a negative electron (mass electron = 1/1700 mass of hydrogen atom) will have sensibly the same atomic weights, but differ widely in chemical properties."

# Conversion of a Brewery Into an Oil Refinery

A Description of the Conversion of a Standard Type Brewery Into  
An Edible Oil Refinery, Utilizing the Equipment  
With Some Alterations and Additions

FOR more than fifty years the George Hauck & Sons brewery at Kingston has been brewing lager beer. It had a capacity of 35,000 barrels a year and was of the standard type of small brewery. For a number of years past the Messrs. Hauck of the present generation and Mr. J. B. Kearney have been considering the unfavorable prospects of small breweries, and early in 1917 they called into consultation Mr. H. E. Brown, a chemical engineer of 115 Broadway, New York, who lives in Kingston. He made a preliminary investigation and his first report offered three plans for the conversion of the establishment into another manufacturing enterprise. These were to engage in either of the following industries:

1. Oils, margarines and lard compounds,
2. The manufacture of maltose,
3. Dairy products, condensed milk, ice creams, etc.

They chose the first, and in June, 1917, Mr. Brown began intensive study of the subject, which continued for two months. Three specific oils were considered, viz., coconut, peanut and cottonseed, and of these peanut oil was recommended. The detailed report gave complete costs of converting the brewery into an oil refining plant. After checking up the report with care independently, it was adopted in its entirety and in September, 1917, the word was given to go ahead. The Hauck Food Products Corporation was organized to succeed the George Hauck & Sons Brewing Co. and in October, 1917, they stopped brewing. Under ordinary conditions they would have been able to begin refining last January, but owing to delays in the delivery of machinery caused by unusual war conditions they were not able to put through the first lot of oil until August, 1918.

The time required for settling in the standard process of refining was a serious problem for their consultant, Mr. Brown. With the room and space available the capacity of the works would be limited, and after careful examination, tests and various consultations with the inventor, he resolved upon the process of refining invented and patented by Dr. Charles Baskerville, head of the department of chemistry of the College of the City of New York.

## RAPID SEPARATION OF FOOTS

The striking feature of the Baskerville process is that instead of allowing the foots to settle and then siphoning off the clear oil, the oil is agitated with wood pulp or cotton linters and caustic solution, and after adding an electrolyte to coagulate the albuminous substances upon the fibers and to harden the soap in the foots, the whole is driven through a filter press, whence the hot oil proceeds immediately to the bleaching apparatus and from there to the deodorizer. Additional details will appear in sequence; it is desired now merely to em-

phasize the need of sufficient speed in the operation to give the works abundant capacity and at the same time to manufacture a high quality product. With this in view Mr. Brown designed a special deodorizer, which is shown in detail and which operates very rapidly. The capacity of the works when certain minor conveniences are installed will be approximately 30 tons of refined, bleached and deodorized oil per day.

Drawings are shown of two cross-sections of the installation which are self-explanatory to those familiar

with both brewing and oil refining. It should be recalled, however, that the main features of a typical beer brewery are as follows:

1. The corn cooker,
2. The mash tun, or tub,
3. The brew kettle,
4. The hop jack,
5. The cooler,
6. Fermenting cellar,
7. Rest cellar (or Ruh cellar),
8. Storage cellars.

These have been transformed or replaced as follows: The corn cooker is replaced by a make-up tank for chemicals.

The mash tun becomes the refining kettle.

The brew kettle was sold and, being made of copper, it brought a good price. It was replaced by the deodorizer.

The hop jack was converted into a bleaching kettle. Fermenting and rest cellars are used for storage of crude and refined oils.

#### UTILIZATION OF STANDARD BREWERY EQUIPMENT

All tanks, except of course those which are porcelain lined, were made available for oil by putting on a special coating made up under amended specifications of a patent designed for other purposes. The combinations of vegetable and bituminous waxes with which brewery tanks are lined will not do for oils. It was necessary also to replace copper piping owing to the action of the metal upon free fatty acids. Steel piping was substituted. The pumps required changes in the packing.

The old mash tub was converted into a refining kettle by adding revolving paddles to the agitators, eliminating the double bottom and providing a coil of steam pipe on the sides for heating. This has a maximum capacity of about thirteen tons of oil. If the crude oil is high in its free fatty acid content, it is desirable to reduce the charge somewhat. First there was pumped into this vessel 17,200 lb. Oriental peanut oil containing 1.28 per cent free fatty acids. Steam was turned on at about 10 a. m. and the process continued under constant temperature control during the refining. Eighty pounds of dry cotton linters were added, the amount being determined by the free acids and albuminous matter present. Then 298 lb. of caustic soda of 24.1 deg. B. was added. Then, as the temperature rose and under constant stirring, 230 lb. of anhydrous salt cake was put in. This is the electrolyte which coagulates the colloidal substances and hardens the flocs upon the fibers of the linters while the clear oil holds them in suspension. The break is easily observed, and after it the agitation is slowed down for ten or fifteen minutes and then the whole is pumped under 60 lb. pressure through a Sweetland self-dumping filter press.

The oil runs through remarkably clear, and while still hot it is led into the bleaching kettle. This is the old hop jack with a stirring apparatus provided and with the requisite steam pipes for maintaining the temperature. No new principle is involved in the process, which carries the oil from simple brightening to water white, as may be desired. Fuller's earth, charcoal or infusorial earth may be employed, according to the results that are called for. When simple brightening is the object, infusorial earth is used. After bleaching the oil is run through a smaller Johnson filter press to remove the medium.

While still hot it is pumped to the deodorizer, the design of which is shown. It contains six coils of steam pipe (of which two are shown in the section), 24 inches in diameter. In the center of one of the coils is a propeller, the revolutions of which keep the oil in constant

circulation. A vacuum of 26 to 27½ inches is maintained above the oil and steam is let into the coils at first at boiler pressure. Then to increase the temperature superheated steam is introduced into the coils and at the same time superheated steam is let into a perforated pipe at the bottom of the apparatus. This passes through the oil, increases the agitation and carries off all the constituents which impart rancid odor and taste. The finish is determined by test samples. The oil is now at a pretty high temperature and would oxidize on contact with the air; therefore in the place of the superheated steam, cold water is introduced into the coils until the desired temperature is reached. The oil is then run into storage tanks and is ready for market.

#### THE SEPARATION OF THE FOOTS IN THE FILTER PRESS

The dehydrated causticized oil is filtered in a dumping Sweetland press, thereby separating the flocs from the refined oil. The cake is carried to a screw press, where 100 lb. per sq.in. force is applied to remove the oil content. The cake, which is now made up chiefly

CROSS-SECTION OF REFINERY

of linters, soap and albuminous matter, is placed in a lead-lined kettle, where it is cut, and the free fatty acids liberated. The whole mass is then agitated and treated with hot water and steam and in this condition

sent to a wood-frame filter press operating on 30 to 40 lb. pressure and the linters separated from the free fatty acids, liquid albuminous matter and slight excess of oils, the cake being thoroughly steamed out, so that only traces of oil and free fatty acids remain with the linters. The mixture of water, free fatty acids and oils is then led to a separating tank, the water separated by gravity, thus leaving the foots in condition to be barrelled, ready for sale to the soap manufacturers. The amount of linters required in refining is so slight that this process is put through only occasionally. The pressed cake is stored until enough for a run is on hand.

the oil is, roughly, the amount of cotton linters needed in the Baskerville process, but this, as has been already noted, must be determined beforehand according to the content of free acid and albuminous matter.

Although it is easier to work with dilute caustic soda, this is not feasible with the Baskerville process because an excess of water tends to produce an emulsion with the soap formed, which is the very thing that must be avoided. The very lively agitation during the refining process and proper care in adding the caustic soda prevent irregularity in saponification and effectively neutralize the free acids. This point is important.

CROSS-SECTION OF REFINERY

This completes the process, but a few notes may be added. Anhydrous salt cake (or Glauber's salt) is used for the electrolyte in the refining process because it is economically available in Kingston. In another plant now in process of installation by Mr. Brown, sodium carbonate is used in place of it, and instead of cotton linters as the mechanical basis for coagulation wood pulp is employed and the foots are to be converted into soap powder. The pulp becomes gelatinized during the process.

Installation is under way to make winter oil in which the refined, bleached and deodorized product is to be piped to a cold storage room and refrigerated to zero deg. C. for a proper time to precipitate the stearines, after which the oils are filtered again, thus producing an oil which remains clear at zero deg. C. One-quarter to one-half of one per cent of the weight of

The company has had difficulty in getting satisfactory filter cloth owing to war conditions. It is necessary to clean the cloths carefully after each pressing inasmuch as the linters make a filter of themselves and unless the cloths are well laundered they clog up. It is planned to substitute Monell metal screens for this purpose.

In regard to margarine, for which among other purposes the oil is available, the laws provide a curious and needless expense. The normal color of good peanut oil is a beautiful yellow, slightly on the greenish shade, like olive oil. But if it is to go into margarine it must be bleached water white and the product, if it is to be yellow, must be colored by the final purchaser. It is a little point made by the farmers that a butter substitute must not look like butter when it is sold save against prohibitory tax. So the farmer colors his butter yellow and the housewife colors her margarine ditto

and we all know that there isn't butter enough to go around.

The plant is half a mile from the railway station and about an equal distance from the docks. To meet this situation a 5-ton tank truck has been provided which loads and delivers that quantity of crude oil in forty-five minutes.

The process requires constant chemical control. Rule of thumb methods will not do.

#### FIGURES ON REFINING LOSSES

In conclusion are given some weighings recorded in connection with the 17,200 lb. of oil which was refined in 32 minutes and filtered in 27 minutes:

|                                                   |                                                           |
|---------------------------------------------------|-----------------------------------------------------------|
| There was added to the oil in the refining kettle |                                                           |
| 80 lb. of linters                                 |                                                           |
| 298 lb. caustic soda. (24.1 deg. B.               |                                                           |
| 18.68 per cent NaOH)                              |                                                           |
| 230 lb. anhydrous salt cake                       |                                                           |
| or a total of                                     | 608 lb.                                                   |
| Wt. of re-pressed cake                            |                                                           |
| foots.....                                        | 909 lb.                                                   |
| Wt. of additions.....                             | 608 lb.                                                   |
| Refining loss.....                                | 301 lb. = $\frac{301 \times 100}{17,200} = 1.75$ per cent |
| Loss of oil = 1.75 — 1.28 = 0.47 per cent         |                                                           |

The foots after pressing weighed 411 lb. This is remarkable, indicating a refining loss of around 1.75 per cent when deduction is made for free acids, linters and the theoretical amount of soda. No weights were determined to check the weight of the brightened and deodorized oil, and it may be that the above figures involve some error.

### Products of the Electric Furnace and the Electrolytic Cell

One of the interesting exhibits at the recent Chemical Exposition was a chart in the booth of the American Electrochemical Society portraying the productions of the electric furnace and the electrolytic cell. This was compiled by Dr. C. G. Fink, past president of the Electrochemical Society. On account of the interest shown in the chart at the Exposition we reproduce it below for the benefit of those who were unable to attend.

| Raw Materials                             | Products                    | Applications                                                                                                                                                                                                                                                              |

### Adhesive Waterproof Drawings and Tracings Without Crimping

BY JOHN S. CARPENTER

**W**ATERPROOFING of drawings and tracings so that they can be used in wet places is done by the use of a preparation composed of gum rubber and benzol.

Benzol dissolves rubber, and the compound thus formed will keep in any climate and under any conditions. As benzol is inflammable, it should be kept in a safe place in a covered jar. If the proper precautions are taken in its use, however, it is not dangerous.

In a quart jar put a piece of rubber about 4 in. square; to this add a half pint of benzol. The rubber will soon swell to three or four times its former bulk and will be ready for use in about 24 hours. To prepare for use take about half the above quantity and put it in another jar for thinning down. If drawings are to be coated use a rather thin solution that will spread well under a brush. The drawing should be coated on both sides. For use as an adhesive, the solution should be fairly stiff, so that if it is desirable afterward to separate the joined parts it can be done more readily than if thin paste is used. There are cases where large tracings and blueprints must be made up of smaller sections, and for this work the paste is invaluable, as the joints will not be crimped out of shape and alignment.

When some of this solution was spilled accidentally on a dirty drawing the benzol was mopped up with a rag and the rubber was rolled up into a ball. The drawing was cleaned very nicely during the operation. This suggested an additional use for the preparation.

Rubber bands instead of pure gum rubber were tried; but it was found that they would not dissolve, merely swelling to many times their former size. Formaldehyde was also tried as a solvent, but its objectionable odor and certain other characteristics have proved it to be undesirable. When diluted as above directed the pure gum paste will not be costly.—*Engineering News-Record*, Sept. 26.

## Nitrogen Fixation Furnaces—II\*

A Discussion of the Operating Technology of Arc Furnaces—Power Factor, Reactance, Air Supply, Increase of Pressure and Oxygen Concentration, Absorption of the Products and the Theory of the Reaction Between Oxygen and Nitrogen

By E. KILBURN SCOTT

THE expanding arcs of electric furnaces give a capacity or leading-current effect, and but for the large amount of reactance used to steady the furnace the power factor would be high. With diverging electrodes the arc at the commencement of each half period is small and gradually lengthens until it breaks, so the resistance may be represented by the rising line of Fig. 14. The low resistance causes the current at the beginning to be large, as indicated by the exaggerated current wave of Fig. 14. When compared with the voltage wave the effect is as if the current were leading, and in practice such is found to be the case. Diverging electrodes also act, with the air between, as a sort of condenser, and a feeble spark is sometimes noticed between the tips of the electrodes where they approach nearest together, which is due to the condenser action.

In the Birkeland-Eyde furnace the interaction of the magnetic field with the alternating current passing between the electrodes is also said to cause the current to lead. The power-factor is certainly higher than with the Schönherr furnace, and this may be due to the latter having a steel tube around the long arc, which gives an inductive effect such as would be the case if armor were placed around a single conductor carrying alternating current. Dr. C. P. Steinmetz considers that the "standing arc" of the Schönherr furnace acts in the opposite way to the expanding arcs of other furnaces, and the resistance of the arc being high at the start causes a current wave distortion which is equivalent to a lagging current.

### REACTANCES

Small choke coils or reactances can be made with adjustable iron cores; also the regulation of series arc lighting can be effected by an apparatus having movable coils. It would be useful to have such readily adjustable reactances for electric furnace working, but as the power required for furnaces is very considerable, it is difficult to keep a movable core or movable coils steady enough, and probably also the core would become too hot.

It is inconvenient to alter the amount of reactance by changing number of turns of a choke coil, because the one connected to the switch contacts would act for the time being as a short circuited secondary, and the large currents which would be induced are difficult to switch. One way to alter reactance while the furnace is running is to change the connections of the coils from series to parallel; another is to have a number of reactances in parallel and change the number of them in

circuit. This latter method is employed for the 4000-kw. Birkeland-Eyde furnaces. When starting such a furnace that has been relined, the method is to switch in only one of three reactors, which allows about 1400 kw. to pass. As the lining dries out the other reactors are switched in one after the other until the furnace receives the full 4000 kw.

During early experiments with a K. S. 3-phase furnace it was considered desirable to interpose transformers of one-to-one ratio between the furnace and the alternating current supply, so that in case any abnormal condition occurred a magnetic link between the two circuits would act as a protection to the alternator. By suitably adjusting the sectional area of the core and the disposition of the coils, the magnetic leakage varied with the current and regulation was very good. The writer understands that reactors on this principle are now used in Norway, the core being built on the lines of a Berry transformer, with groups of plates radiating from a central core around which are coils of circular shape. The magnetic forces are thus balanced, and the coils always retain their position.

Although many reactors are built with iron cores, there is a tendency to dispense with the iron because reactors without it are more accessible, and as the conductors are of bare copper supported in cement concrete they are fireproof. They have to be placed away from structural steelwork. One form of coil known as a "toroid" has the advantage of giving the greatest amount of self-induction with least amount of electrical resistance. It consists of bare copper strip wound concentrically into a flat coil with the turns spaced well apart and set in cement concrete.

A neat form of reactor made by the General Electric Co. is shown in Fig. 15. The conductor is bare copper wire, wound in slightly conical layers, the turns of the first layer progressing from outside to inside and of the second layer from the inside to outside, and so on. The layers converge where the voltage is a minimum, the clearance between turns being about an inch (2.5 cm.) for 6600 volts. The concrete is freed from metallic particles and cured in the presence of high pressure steam, and the whole is supported from the ground by porcelain post insulators.

### AIR SUPPLY

The yield of a furnace depends to some extent on the condition of the air blown through the arc, for if charged with dust particles, moisture or oil, or the acid vapors of large industrial centers, results are not so good as when the air is clean and dry. While working an experimental plant in Manchester, England, it was found that the yields on moist days were lower than

\*Completion of the paper read at the thirty-fourth general meeting of the American Electrochemical Society, held at Atlantic City, N. J., Sept. 30, 1918.

when the atmosphere was comparatively dry. The air should have an easy flow from the blower to the furnace, that is to say, pipes should be as short and straight as possible, and the branches of similar length, so that each furnace may receive the same pressure.

Expanding nozzles have been recommended for delivering air to the flame, but the writer has found them liable to set up throbbings in the air flow. To get even flow, the pressure at discharge has to be about half the initial pressure, and this condition is not easy to meet with air at low pressure and high velocity, because the expanding portion has to be excessively long. Air compressors of the reciprocating type are not suitable for the supply of air to nitrogen fixation furnaces, because the air must flow in an absolutely steady stream and be free from oil, etc., also such compressors are only ef-

FIG. 14. SHOWING THE EFFECT OF ARCS WHICH INCREASE IN RESISTANCE

ficient for pressures above 15 lb. per sq.in. (1 atmosphere). Pressure blowers such as the Root type may be used, but as they also work by pocketing air and carrying it over to the delivery side, the pressure is somewhat uneven. They work efficiently with pressures up to about 8 lb. per sq.in. (0.5 atmosphere). Fans give steady flow, but are inefficient because they do not use the velocity energy of the air at the impeller exit. Also they are only efficient for pressures below 1 lb. or so per sq.in. (0.07 atmosphere).

Centrifugal compressors are a good type, because they are efficient and deliver a steady stream of air at pressures necessary for the furnaces. They resemble a centrifugal pump in having a rapidly rotating impeller surrounded by a stationary set of discharge vanes supported by the casing. For pressures up to 4 lb. per sq.in. (0.25 atmosphere) one impeller is used, and higher pressures are obtained by merely multiplying the number of impellers. The speeds are suitable for coupling them direct to either steam turbines or 60-cycle induction motors. With 25 cycles the motor speeds are lower and gearing has to be used.

#### POWER FOR CENTRIFUGAL COMPRESSOR

The amount of power required to blow the air through the furnaces depends on the pressure, but it is usually less than 3 per cent of the energy which is supplied to the furnaces. The theoretical horsepower required to compress adiabatically 100 cubic feet of air (3 cu.m.) at atmospheric pressure is given by the curve Fig. 16. It will be noted that it is not a straight line. Assuming that a 10,000-kw. factory requires 700,000 cubic feet (20,000 cu.m.) of air per hour, or 11,660 cu.ft. (330 cu.m.) per minute, then for a pressure of 5 lb. per sq.in. (0.33 atmosphere) the power is

$$\frac{11,660 \times 2}{100} = 232 \text{ theoretical horsepower.}$$

A centrifugal compressor for this duty would have two stages, and run at about 3450 rev. per minute with an efficiency of 70 per cent, so about 400 shaft horse-

power would be required. Allowing for efficiency of the motor, about 200 kw. would be supplied, and it will be seen that even at 5 lb. pressure the energy taken by the centrifugal blower is only about 2 per cent of the energy put into the furnaces.

The high speed of the centrifugal compressor makes it suitable for being driven by a steam turbine, and if the turbine is supplied with steam at 120 lb. per sq.in. (8 atmospheres) the consumption of steam may be assumed at about  $200 \times 18 = 3,600$  lb. (1,630 kg.) per hour.

#### PREHEATER

Preheating the air before it enters the furnace is advantageous because it raises the average temperature of the arc, and electrical operation is improved owing to the air being already in an ionized condition. With preheat the velocity of the air can also be lower than when the air is cold. For a given production of nitric acid the electric energy used is rather lower with highly preheated air.

The Schönherf furnace has a preheater combined with it, which takes the form of several annular tubes of steel around a central reaction chamber, and the entering cold air and the exit gases pass through these tubes in counter-current directions. As the gases leave the reaction chambers at over 1000 deg. C. it is possible to give a very high preheat to the entering air. At Saaheim, in Norway, there are 96 of these furnaces of 1000 kw., each one with its own preheater. The Birkeland-Eyde furnace has also a preheater, because the air passes into the reaction chamber through a large num-

FIG. 15. REACTOR MADE BY THE GENERAL CHEMICAL COMPANY

ber of small holes in the refractory chamotte lining. As the electric arc keeps this lining at red heat, the entering air is preheated somewhat before it strikes the arc. This lining constitutes one of the objections to this furnace, because it is expensive to build and takes several days to dry out.

In several ways it is an advantage to employ a separate preheater, to serve a number of furnaces, one reason being that it can be designed efficiently to give the heat exchange. Also, hot air is always available in starting a new furnace, for when a furnace has its own preheater some time must obviously elapse before heat is available to warm up the incoming air.

It is usual to employ boilers to utilize the bulk of the heat from the furnace gases in raising steam. If the gases leave the boiler at 250 deg. C. and a further 150 deg. C. is absorbed in the preheater, then the preheater may be made of steel. At the same time it is advisable to have it in several units so as to take care of the expansion due to difference in temperature at the two ends. Thin steel tubes may be used, and the air should pass around them.

#### EFFECT OF ADDING OXYGEN

By weight air consists of 23 per cent oxygen and 77 per cent nitrogen; or by volume 20.7 per cent oxygen and 79.3 per cent nitrogen. One pound at 62 deg. F. and barometer at 30 inches occupies 13 cu.ft. (1 kg. = 0.81 cu.m.). One pound of oxygen at 62 deg. F. occupies 12 cu.ft. (1 kg. = 0.75 cu.m.), and is contained in 56 cu.ft. of air (3.5 cu.m.).

FIG. 16. CURVE GIVING THEORETICAL HORSEPOWER TO COMPRESS AIR

It is an advantage to add oxygen to the air passing through the furnace, because the concentration of nitric oxide is a maximum when the product of oxygen and nitrogen is also a maximum. It can be shown that it is directly proportional to the square root of the product; thus the equation for air is:  $0.21 \times 0.79 = 0.16$ . And for equal parts of oxygen and nitrogen  $0.5 \times 0.5 = 0.25$ . The increased yield is therefore 20 per cent, as shown by the ratio:

$$\sqrt{16} : \sqrt{25} :: 100 : 120$$

Commercially it is only possible to add oxygen when the process is worked in a closed cycle, the amount required continuously being then only that which the nitric oxide takes up.

If we assume that a factory utilizing 10,000 kw. requires 700,000 cu.ft. of air (20,000 cu.m.) per hour then 21 per cent of this, equal to 145,000 cu.ft. (4140 cu.m.), represents the oxygen. After passing through the furnace the air contained about 1.5 per cent nitric oxide of which about half is oxygen. The oxygen does not have to be pure, and if the oxygen-producing apparatus makes a mixture of 75 per cent oxygen and 25 per cent nitrogen, then about 1 per cent of the 145,000 cu.ft. (4,140 cu.m.), or, say, 1450 cu.ft. (41.4 cu.m.), per hour will have to be added continuously.

Addition of oxygen (to the air) is equivalent to increasing its pressure, for in air it occupies only one-fifth of the volume, whereas when it is equal with the nitrogen it occupies half of the volume. The effect is, therefore, the same as increasing pressure  $2\frac{1}{2}$  times, be-

cause much more oxygen is passed through the furnace. This is equivalent to  $14.7 \times 2.5 = 35$  lb. per sq.in. (2.4 atmospheres), yet at the same time the furnace walls do not have to withstand any extra pressure.

Pure oxygen and hydrogen can be made by electrolysis, but it requires a great deal of direct current. Also pure oxygen and nitrogen can be made from liquid air, but this requires much machinery and power. In some cases, however, oxygen made by these methods is a by-product of other manufacturing processes. Thus oxygen is a by-product of plants making hydrogen for fat hardening; also it is a by-product in the manufacture of calcium cyanamide, because that process only requires pure nitrogen. Where it can be obtained such by-product oxygen should be cheap.

Hitherto the manufacture of oxygen has been practically a monopoly and in consequence prices have been kept at a high level and little improvement made in methods of manufacture. In the near future there is every possibility of oxygen being produced in larger quantity and much cheaper. The Jefferies-Norton process for air separation makes use of liquefaction and distillation, but it has new features in the method of heat exchange and in the still. In general appearance the apparatus is very similar to the Claude system, but an essential difference is that the major part of the nitrogen is not expanded but issues at its original pressure. The nitrogen is heated and then expanded in a gas engine to furnish power to drive the plant; thus no outside power is required, as the heat applied to the nitrogen develops all that is necessary to drive the compressors.

It is possible also that the centrifugal method of separating the gases of air may be made a commercial success. This acts on the difference in weight of oxygen and nitrogen. It should be noted that a mixture of oxygen and nitrogen will do so long as the oxygen is in excess.

#### EFFECT OF INCREASING PRESSURE

It is known that increased yields can be obtained by increasing pressure in the reaction chambers of arc furnaces, but hitherto the pressures used have been sufficient only to move the air quickly through the arc. Extra pressure means more power to drive the centrifugal compressor, and the question is whether a larger plant requiring more power to work it would be justified by the increased yields obtained. Concentration is about doubled at 100 lb. pressure.

In any case there is no need to use such "heroic" high pressures as 1500 to 2000 lb. per sq.in. (100 to 135 atmospheres) which are necessary for the Haber process of making synthetic ammonia. Such pressures can be dealt with on a laboratory scale, with small tubes and apparatus, but they are troublesome on a large scale. It is difficult to retain hydrogen and to prevent it forming an explosive mixture with oxygen, also it occludes into the steel casing and makes it brittle.

Air at high pressure has a greater insulating value than air at low pressure, as shown by the fact that sparking between the metal quadrants of an electrostatic voltmeter may be stopped by merely increasing the air pressure. Owing to lower pressure at high altitudes the corona effect on transmission lines is also more pronounced.

It should be noted that a small pressure is caused by the explosions from the arcs in the furnace. When a furnace is first started up these are very pronounced and of varying intensities, but after the furnace is heated the explosions become less intense and more numerous.

#### ABSORPTION

Fig. 17 is a diagram indicating the approximate temperature of the gases as they pass through the system, when it is desired to make nitric acid. Boilers reduce the temperature from about 1000 deg. C. to 250 deg. C., and a heat exchanger then reduces the gases to about

FIG. 17. SHOWING FLOW OF GAS AND AIR AND APPROPRIATE TEMPERATURE

100 deg. Finally a water cooler brings them down to 40 deg. C. or lower. The final temperature obviously depending on the temperature of the cooling water, it would probably be possible in winter to reduce the temperature to about 20 deg. C. The lower the temperature of the gases in the absorption towers, the better is the absorption, and that is the reason why stronger acid is obtained in winter than in summer.

As the gases leave the furnace they are at high temperature and must be carried in ducts lined with firebrick. Between 250 deg. C. and 100 deg. C. steel may be used, but below 100 deg. C it is well to use aluminium or acid-proof stoneware, as silicon-iron cannot be used. The water cooler should also have aluminium pipes, as acid may form. Before the gas enters the towers it is

necessary to facilitate the oxidation of all the nitric oxide to nitrogen dioxide, and for this purpose large open spaces are necessary through which the gases can flow sluggishly.

It is of some assistance to have connecting pipes of large cross-section. At Rjukan II, Norway, the furnaces are about 3000 feet (0.9 kilometer) from the absorption towers and the gases are carried through an aluminium pipe about 3 ft. (0.9 m.) diameter. The gases enter the pipe at about 200 deg. C., and are cooled down considerably while passing through it.

With gases at 40 deg. C. and 1.5 per cent nitric oxide concentration, the nitric acid can be easily made to about 33 per cent, which is correct strength for the manufacture of ammonium nitrate and calcium nitrate.

When sodium nitrite is required, the gases must enter the absorption towers at about 250 deg. C., because at this temperature only about half the nitric oxide has been changed to nitrogen dioxide and this mixture when absorbed by sodium carbonate or caustic soda gives sodium nitrite without any nitrate. For this product the absorption towers can be much smaller than those for making nitric acid, and they are also cheaper because they can be made of steel plate instead of acid-proof brickwork. Considerable quantities of sodium nitrite are required for the aniline dye industry, and it is also used for drugs and the pickling of meat, etc.

#### COOLING THE GAS

The chemical reaction of nitrogen and oxygen is reversible, but the tendency for nitric oxide gas to dissociate is only slight at below 1500 deg. C. The problem is therefore to jerk the nitric oxide from arc temperature to below 1500 deg. C. To a certain extent this is performed automatically by the air which surrounds the arc streamers, and it is probably most effective just at the moment when the arc breaks. Passing the air at high velocity through the flame is also advantageous, and at the same time the fixed gas and air should be withdrawn from the top of the furnace by an exhaust fan.

Several ways have been employed for expediting the cooling; for example, in the Pauling type of furnace some of the cooled gases are re-introduced again at a point just above the zone of maximum temperature. Another method is to impinge the top of the arc flame into a cooler, which may take the form of a steam boiler. During experiments with an early model of the K. S. 3-phase furnace, a boiler was set low enough for the electric arc flames to play against the tubes, when it was noted that they flickered about the surface much the same as do the flames of ordinary coal gas, and the boiler was not detrimentally affected. This plan takes advantage of the latent heat of steam, and the cooling is just as good in a large furnace as a small one. The boiler or cooler is connected to earth, but as the center of the flame is the neutral point of the 3-phase system no current passes, as the phases are in balance. As a matter of fact, the bulk of the electrical energy delivered to a furnace passes between the electrodes near the bottom of the flame.

#### STEAM FROM BOILERS

The most economical way to cool furnace gases is to pass them through boilers and to employ the steam so produced for various purposes in the factory, such as

evaporating water for the end products, etc.; also, as indicated below, the steam may be used to generate electric energy and so work regeneratively.

In order to show how much steam can be raised by the heat of furnace gases it may be of interest to give some figures for a plant equipped with furnaces to utilize 10,000 kw. and supplied with about 700,000 cu.ft. of air (20,100 cu.m.) per hour. At atmospheric pressure the volume of air containing 1.5 per cent of nitric oxide gas would be about 12.5 cu.ft. per lb., and therefore 700,000 cu.ft. (20,100 cu.m.) will weigh

$$\frac{700,000}{12.5} = 56,000 \text{ lb. (25,500 kg.)}$$

Assuming that the air and the nitric oxide enter the boiler at about 1000 deg. C. (1800 deg. F.) and leave at 250 deg. C. (450 deg. F.), then the difference of temperature is 750 deg. C. (1350 deg. F.) The specific heat of air is about 0.24, so the total heat in B.t.u. will be  $1,350 \times 0.24 \times 56,000 = 18,000,000$  (4,500,000 cal.) Assuming that about 970 B.t.u. are required to evaporate a pound of water into a pound of steam at atmospheric pressure, the steam will amount to

$$\frac{18,000,000}{970} = 18,500 \text{ lb. per hr. (8400 kg.)}$$

Allowing for loss by radiation through the brick-work setting and the steam drum, the total steam may be assumed at 18,000 lb. (8200 kg.) per hour.

Steam at 125 lb. per sq.in. (8.5 atmospheres) is suitable for evaporating purposes, and if the steam has to be carried some distance it is well to add about 50 deg. F. of superheat, making a total temperature of about

$$350 + 50 = 400 \text{ deg. F. (200 deg. C.)}$$

In a very large installation, more steam may be generated than is required for evaporation of end products, and in that case it can be used for generating electric energy. In the latest installation at Rjukan II, in Norway, there are three 4000-kw. steam turbine alternators supplied with steam by the hot furnace gases. It is very significant that in an installation having practically unlimited water power, steam turbines should have been installed, and indicates the saving there would be by combining an air nitrate factory with a power house equipped with steam turbines.

If all the steam from a 10,000-kw. plant was to be used in turbo generators having a steam consumption of say 18 lb. (8.2 kg.) per kw.-hour, then the energy would be

$$\frac{18,000}{18} = 1000 \text{ kw.}$$

That is to say, about 10 per cent of the energy put into the furnaces can be regenerated.

The boilers may be of any pattern so long as they are gas-tight, and they may form part of the furnace, or be separate, as in Norwegian installations. The feed water should be hot, so that moisture may not be deposited on the tubes, and for this purpose the water used for cooling electrodes and gases is employed and there is a further saving of heat.

In many discussions on the subject of nitrogen fixation in arc furnaces it has been assumed that the sole factor bringing about formation of nitric oxide is a thermal one. This is very doubtful, however, because all data relating to the laws of thermo-dynamic equilib-

rium have been obtained at temperatures very much lower than those commonly met with in electric furnaces; therefore it does not follow that the same laws hold good for arc temperature.

Dr. Maxted states, in the proceedings of the Society of Chemical Industry for April 15, 1918, that:

"Purely thermic interpretation of the nitrogen oxide reaction depends on a large extrapolation from lower to higher temperatures, and assumes that no latent factors cause increase or decrease in the observed temperature coefficients."

Some experiments by Mr. J. L. R. Hayden (see Trans. A. I. E. E., 34, 613) lead him to the conclusion that in fixing nitrogen by the electric arc the conditions of thermo-dynamic equilibrium are of secondary, if of any, moment. In other words, the process is essentially an electric one. His experiments were made with electrodes of various material which gave different temperatures, and the order of their nitric acid production was as follows:

| Concentration | Boiling Point<br>(Arc Temperature) |
|---------------|------------------------------------|
| Iron—Highest  | 2450 deg. C.                       |
| Titanium      | 2700 deg. C.                       |
| Carbon        | 3600 deg. C.                       |
| Copper—Lowest | 2310 deg. C.                       |

It will be seen that although carbon gives the highest arc temperature it is relatively inefficient in producing nitric oxide. Also the iron and copper, which give approximately the same arc temperature, are at opposite ends of the scale in producing oxide.

Another experiment made with the mercury arc, which has a much lower temperature than the above, showed that it was easily possible to get concentrations above those representing thermo-dynamic equilibrium. In electric furnaces there are other phenomena besides that of heat, for example, ionization, which appears to have the effect of disrupting the nitrogen molecules and so facilitating their combination with surrounding oxygen. It is conceivable also that the electric stress due to the high voltage and the magnetic field set up by the currents may have some effect.

Mr. Cramp, of Manchester, found that there was an increase of nitric oxide when ozone was added to the air passing into the arc flame, and it may be that  $O_3$  and the corresponding polymer of nitrogen, which Sir J. J. Thompson calls  $N_p$ , are formed momentarily, and then, dissociating, the nascent atoms of oxygen and nitrogen combine.

### Platinum Released

Under an order of Nov. 14 from the Bureau of Mines, licenses will no longer be required in connection with the handling of fireworks or the precious metals platinum, iridium and palladium. Many of the numerous chemicals entering into the manufacture of explosives are used constantly for other purposes, and under the new order no restrictions will obtain on the handling of these chemicals when not used in the manufacture of explosives. Licenses are still required for the handling or all such ingredients when intended to be used in explosives manufacture, however.

The explosives regulation was passed by Congress in October, 1917, with the aim of putting a stop to the numerous incendiary explosions and fires occurring at war munitions and other industrial plants.

## Helical and Elliptical Springs\*

A Discussion of the Manufacture of Elliptical and Coil Springs—Types of Steel Alloys Used—Methods of Testing—Formulae of Calculating Loads, Deflections and Torsion—Effect of Overstrain—Molecular Hysteresis

By CHAUNCEY T. EDGERTON

A SPRING may be defined as a device for the storage or re-distribution of mechanical energy. That may not be a very scientific definition, but it will at least serve to point the distinction between the two general classes of springs; first, those subjected to transverse stress, and, second, those subjected to torsional stress. Springs coming under class 1 are usually made of flat steel, in which one dimension of the section is much greater than the other. The common example of this class is the usual railroad "leaf" or "elliptic" suspension spring, and a similar type is, as you know, the standard spring for automobile suspension.

This paper will be largely confined to these types, from lack of time to speak of the many interesting kinds of special springs—of volutes, very popular as railroad suspension and buffer springs in Europe and which give such splendid results when properly made; of safety valve springs, which are often ordered to a tolerance of  $\frac{1}{16}$  in. on the loaded height, and so carefully made are the springs and so accurate is our working theory that they can be figured almost to a dot; of indicator springs, on which the requirements are so severe that the manufacturers think they are doing well if they get one spring right in ten.

### MANUFACTURE OF ELLIPTIC SPRINGS

I will run briefly through the series of operations involved in the manufacture of elliptic springs before taking up a few interesting points connected with the design. The plates are sheared to length cold in a slider-head shear, and then are either punched or nibbed at their center. (Automobile spring plates are usually bunched and assembled with a bolt or rivet. Railroad spring plates have a little conical nib pressed up in the center; the nibs of adjacent plates nest into each other and lock the plates together.) Next the main plate of the spring has an eye rolled up on each end, or else it has a drop-forged pad welded to each end, or some other means is provided for engagement with the hangers. Usually two or three plates besides the main plate are cut the full length of the spring; the remainder of the plates are regularly shortened, or "stepped." These are usually tapered down at each end in tapering rolls, and trimmed off square, half round or pointed. The plates are then ready to be fitted.

From time immemorial, elliptic springs have been fitted by hand. Even now the great majority of railroad springs are so fitted, while with automobile springs, the proportion of those machine fitted is somewhat

greater. Spring fitting is more nearly a skilled labor proposition than any other major operation in a spring mill, and a good fitter is a fairly well-paid mechanic.

Elliptic springs of alloy steel are hardened and drawn in pyrometer-regulated furnaces and baths, but carbon steel springs (that is, the vast majority of railroad elliptics) are hardened and tempered in a single operation, each plate going into the tempering oil as soon as it is fitted, without being re-heated. The hardening medium used is rather mild—either common black mineral oil or something like "Haughton's Soluble," and it should be hot—about 300 to 350 deg. F. The "drawing" operation varies in different shops. Many good fitters "flash" the plates; that is, they withdraw each plate from the oil after an immersion of about half a minute, so that it still retains heat enough to ignite the oil which adheres to it. Of course the flashing itself does nothing to the steel; it is simply an indication that the plate retains heat enough to draw itself down to a spring temper. Other fitters leave the plates in the oil until cold, and then draw them in a low-temperature furnace to the proper color. The plates are then ready to be banded or bolted together, and the spring tested.

It is surprising to find what excellent and uniform results a good fitter will obtain with this seemingly primitive method of heat treatment. When I was conducting experimental work in the shops, I used to go around occasionally after the fitters had gone home, and steal half a dozen tempered plates at random from their tables. The next day I would give these a transverse load test; and while they would not average up quite so well as heat-treated plates, I would find occasional specimens which on static test would equal the best results I could obtain from the most careful heat treatment. There is, of course, no good reason why this should not be so. The one great advantage obtained from careful heat treatment is uniformity. If the average excellence of the various plates in an elliptic spring determined the life of the spring, the advantages of special heat treatment over the handiwork of a first-class spring fitter would be but slight. The trouble is that an elliptic spring is only as strong as its weakest plate.

I also used to test these flat plates to destruction under repeated loads, alternating from zero to a fixed maximum stress. In these tests the difference between hand-tempered and specially treated plates was more marked than in the static tests. Pyrometer treatment would usually give a fairly uniform life before failure, while the life of hand-tempered plates was decidedly erratic.

All springs made from alloy steels are given special pyrometer heat treatment. After the plates are fitted they are allowed to cool, and are then reheated in a

\*Read before the Pittsburgh Section, American Electrochemical Society, May 10, 1918.

special furnace, preferably of the muffle or semi-muffle type. They remain in the quenching oil till cold, and are then drawn to spring temper in a lead or salt bath or a low-temperature furnace also regulated by pyrometer. In some automobile spring shops I understand they provide a bank of three furnaces for each fitter—one for heating to fit, one for heating to quench and the third for drawing. Personally I prefer to make the heat treatment an independent operation. I had excellent success with a treating furnace built as shown in Fig. 1. These furnaces heated uniformly and quite rapidly—much more so than a muffle fire. It is important to have the heating chamber amply large. If it is too small or if the arch is too low, the heat will be "spotty" and it will be very difficult to bring a charge of any size up to heat without losing control of the temperature.

Speaking from a commercial standpoint, the problem of high temperature regulation and measurement is not so much a question of knowing what temperature you have in your furnace as of insuring that the work, or charge, is at furnace temperature. This is particularly true with material like elliptic spring plates, which have to be handled very gingerly when they are hot, so as not to change their camber and destroy the "fit." It is necessary to put a number of these plates into the furnace at a time in order to secure reasonable economy

took considerable time and cost some money, but the results were worth it.

For the drawing operation there is nothing like a lead or salt bath. A furnace is difficult to regulate at the low temperatures desired, owing to the small body of contained heat in the furnace; whereas a lead bath such as we use in a spring shop contains two or three tons of lead, making a heat reservoir capable of very accurate control and yet capable of being brought up to temperature in a reasonable time.

#### COMPOSITION OF SPRING STEEL PLATES

The standard analysis of carbon spring steel is:

Carbon .....0.90 to 1.10 per cent

Manganese .....Less than 0.50 per cent

Phosphorus and sulphur. Less than 0.05 per cent

For carriage and wagon spring work the carbon is often lower, so that the plates can be dipped in water. For railroad elliptics most mill men prefer carbon not over 1 per cent. You are all doubtless familiar with the long-standing prejudice in favor of low phosphorus and sulphur. I am more afraid of high manganese in spring steel than of high phosphorus. I believe some authorities claim that it takes about 0.25 to 0.30 per cent of manganese to thoroughly de-oxidize the melt, that this is the sole function of the manganese content and that any higher manganese serves no good purpose. I have always obtained best results from steels running 0.30 to 0.40 per cent manganese; toward 0.50 per cent I begin to look for trouble.

Of the alloy steels the favorites for high grade elliptics are chromium-vanadium, chromium-nickel and silico-manganese. These are used mostly in automobile work, although a few railroads use chromium-vanadium steel for some or all of their elliptic springs. The Ford people claim that after exhaustive experiments they have demonstrated chromium-vanadium to be the very best for springs, and they use nothing else. Several other leading automobile concerns use the same types; perhaps a larger number use silico-manganese. There are several varieties of chromium-nickel spring steel, but not much is used, and I know very little about it from personal experience.

Chromium-vanadium spring steel, as originally proposed by the American Vanadium Co., analyzed 0.40 to 0.50 per cent carbon, about 1.25 per cent chromium, about 1.00 per cent manganese and 0.20 per cent vanadium. This made a very tender material, of most remarkable physical qualities if treated properly, but it is a little difficult to get the right treatment. One of the big producers has kept pretty close to this original analysis, simply reducing the chromium to an average content of about 1.10 per cent. Other steel makers, after lots of trouble with spring makers who couldn't or wouldn't heat-treat properly, now make chromium-vanadium steel containing about

0.43 to 0.52 per cent Carbon

0.80 to 1.10 per cent Chromium

0.60 to 0.80 per cent Manganese

still it is quite tender. That and its cost are the two objections to its use in springs. If properly treated and cost is no object, it is a wonderful steel.

FIG. 1. CROSS-SECTION OF HEAT-TREATING FURNACE, LOOKING TOWARD REAR.

of operation; and as it is impracticable to have more than one or two pyrometer fire ends in each fire if you are operating a bank of fires, success depends much on the experience, skill and judgment of your pyrometer man.

As far as the actual reliability of the pyrometers is concerned, good results may be obtained in any one of several ways, but they all involve much care and constant checking. I still believe that the way I adopted when handling this work was the best. After several heart-rending experiences I bought a first-class high resistance millivoltmeter, had my own couples made up by a handy little German machinist in our own shops and calibrated them from a "standard" couple, thoroughly seasoned by long exposure to high temperatures and calibrated direct from three or four freezing-points. The points used were those of eutectoid steel, common salt, sodium sulphate and barium chloride. These gave a range covering the quenching temperature of any kind of spring steel; they were materials easily obtained and with well-defined freezing points. This practice

Silico-manganese spring steel, as usually made in this country, is modeled after the French Le Moyne and the Austrian Poldhi steels. The analysis is:

|                |                       |
|----------------|-----------------------|
| Carbon.....    | 0.50 to 0.60 per cent |
| Manganese..... | About 0.80 per cent   |
| Silicon.....   | 1.80 to 2.00 per cent |

This is not so tender a steel as chromium-vanadium. Some metallurgists are skeptical about the anti-fatigue qualities of silico-manganese steel, but it is in high favor as an automobile spring steel, and with the most ordinary care in heat treatment will make a very good record.

#### TESTING ELLIPTICAL SPRINGS

Before passing on to helical springs, just a word or two about the testing of elliptical springs. The usual design-stress for railroad elliptics is 70,000 lb. per sq.in., under the carbody or engine load; and it is customary to give the springs a static test before shipment of 50 to 100 per cent over the working load. Autographic tests on springs in service indicate that on an average roadbed a well-designed spring will suffer a maximum deflection under shock and vibration of not more than 50 per cent in excess of the static deflection under carbody load. Frequently, however, the vibration due to inequalities of roadbed cause an absolute deflection in the springs of  $\frac{1}{2}$  in., 1 in., 2 in. or some other figure which bears no particular relation to the deflection under carbody load; or, in other words, this absolute deflection would be about the same if the design of the spring were changed so as to make it more flexible or less flexible. But if the spring is made more flexible, any absolute deflection of  $\frac{1}{2}$  in., 1 in., 2 in. or whatever the maximum may be will be a smaller percentage of the deflection under rated load; and conversely the percentage will be greater in a less flexible spring. But with the rated load at a fixed fiber stress, this is tantamount to saying that a flexible spring will be subjected to smaller maximum stresses than a stiff spring; consequently the life of the flexible spring will be longer. This all seems self-evident; and yet you would be surprised to find how impervious many spring users are to this simple argument. They will look at nothing but the design-stress for the carbody load; if that is all right, then the spring is all right.

The condition I have just described is greatly exaggerated in automobile service, where the road conditions are far more severe than in railroad work. An automobile spring should be designed so that it will stand an indefinite number of deflections to the point where it will hit the frame or the rubber bumpers.

I have already spoken of the transverse tests I made when engaged in investigation work. I made hundreds of these, both static and fatigue tests, under all sorts of conditions. Needless to say, I obtained some very interesting results, but only have time now to refer to one or two of these.

When the chromium-vanadium spring-steel people began to visit us and talk their product, their favorite piece of propaganda was to take a piece of their steel eight or ten inches long, heat-treat it very carefully and then break it transversely. They would then show us the peculiar long "scarf" formed by the break, the fibrous,

hickory-like appearance of the fracture, ask us to compare this with the square break and crystalline structure of carbon steel in a similar test, and invite our reverent admiration for their wonderful steel. This was duly forthcoming until I began to make some fatigue tests on this same steel. Then I found that these plates, tested under repeated loads which were well within the elastic limit, broke with a clean, square fracture, showing no trace of that wonderful "hickory" fiber. What became of this fiber? I have never found a conclusive answer to the question. My own guess is that the fiber is a condition set up by the rolling, which gradually disappears as the metal becomes fatigued.

These fatigue tests would distinguish between "mild" and "tender" steels very consistently. Chromium-vanadium steel would often make an excellent showing in static tests over a considerable range of treating temperatures, but when the same heat of steel was put through fatigue tests the treatment had to be right within a very narrow margin to get anything like maximum results. On the other hand, carbon and silico-manganese spring steels would show long life over a comparatively wide range of analysis and heat treatment.

#### CALCULATION OF ELLIPTIC SPRINGS

The formulæ for the calculation of elliptic springs, as laid down in the text books, are tolerably correct. The load formula is:

$$P = \frac{2 S b h^2 n}{3 L}$$

where P is the load at the center of the springs, S is the corresponding fiber stress, b and h are the width and thickness respectively of the plate section, n is the number of plates, and L is the effective length, with the width of band deducted. The deflection formula for a semi-elliptic spring is:

$$\text{Deflection} = \frac{3 P L^3}{48 E h^3 n}$$

E being the elastic modulus of the material. For a full elliptic the deflection will, of course, be twice as great. The deflection formula is approximately correct only when the plates are spaced according to theory. Most mill men use empirical deflection formulæ, and on a lot of any size they set up a trial spring before fitting the lot, as the deflection is subject to several disturbing practical conditions which make it difficult to figure accurately.

#### MANUFACTURE OF COIL SPRINGS

We come now to the second grand division of springs—those which are subjected to torsional or twisting stress. The majority of these are helical springs, or, as they are generally known in the trade, coils. They are further classified into extension or compression springs, according to the nature of the loading applied; this classification has nothing to do with the nature of the stress produced in the material. They are also divided from a manufacturing standpoint into hot-wound and cold-wound springs; if the material is larger than  $\frac{3}{8}$  in. round or square they are usually wound hot, while the smaller sizes are wound cold. The material

used may be either round, square or rectangular in section, and our English cousins rather favor certain sections of irregular shape. Railroad bearing springs as used in this country are practically all round-section compression springs, hot wound.

The manufacture of these springs is quite simple. The bars are cut to the proper length, and each end tapered down in a big tapering roll, each of these tapered ends having a length of about three-quarters of a turn of the finished springs. The bars are then wound or coiled on a cylindrical mandrel with just enough taper to permit of sliding the spring off without distorting it. The pitch is regulated by feeding the bars into the machine in direct contact with a revolving grooved worm; where very accurate pitch is required, the bars are fed in through a worm-driven feed carriage, similar to the leadscrew and tool-carriage of a lathe. The springs are then dressed, so that the tapered ends lie flat and square, and are then quenched in the tempering oil. In ordinary commercial work it is not necessary to flash or draw the springs, as the oil gets pretty hot, and the size of the steel is usually such that it does not cool fast enough in the oil to get very hard. The springs are then tested solid, or coil to coil, two or three times, also tested for load if any is specified.

Small lots of wire springs are wound on a lathe in lengths up to the capacity of the machine. They are then cut to length, the ends heated over a little slot furnace and dressed in by hand, and ground to a bearing on an emery wheel. Large lots are coiled in automatics, in which feed-rolls drive the wire onto a stub mandrel, around which it is bent by rollers. The dressing of the ends is done automatically, the "pitch plug" dropping back every so many coils and allowing one coil to be wound close. Some automatics also cut the springs off. On small sizes these machines will turn out two or three thousand springs an hour, coiled, dressed and cut, ready for grinding. It takes some time to set up one of these automatics for a job, so that they are not economical on small lots.

It is customary to draw wire springs after winding to a dark blue color (about 500 to 550 deg. F.). This is termed "blueing." It tends to relieve the strains due to the winding, and also provides more or less protection against oxidation in case the springs are not to be japanned. However, a japanned finish is the usual one for wire springs, and it so happens that a japan which bakes at 500 to 550 deg. F. has just the right elasticity and toughness for spring use. Therefore the operation of baking the japan also serves to draw the springs. In modern wire spring shops the japanning ovens are built large enough to accommodate a small truck fitted with racks, on which the springs are hung after dipping, and the truck is then run into the oven and left until the baking is completed.

#### COMPOSITION OF STEELS FOR COILS

Coil springs of alloy steel are heat-treated in practically the same manner as elliptics. The analysis of steel used, either carbon or alloy, is about the same as for elliptics, although carbon steel for coils should preferably run above 1.00 per cent in carbon rather than below.

The manufacture of cold-wound coils is an entirely different matter. You cannot coil 1.00 per cent carbon

steel cold, even though you carefully anneal it. Therefore several special grades of "carbon spring wire" are used for making such springs. Most important of these are oil-tempered wire, and hard-drawn or "black premier" wire. The former is a wire running about 0.50 per cent carbon and 0.50 to 0.50 per cent manganese, and is heat-treated directly after passing through the wire dies and before winding on the reel, by being passed successively through a muffle furnace, a quenching bath and a drawing bath or furnace. This tempered wire can then be wound cold on practically any size of mandrel, and can even be battered with a hammer until the wire is bent almost double on itself without breaking. At the same time it is good for a torsional stress of 110,000 to 115,000 lb. per sq.in., in  $\frac{5}{16}$  in. or  $\frac{3}{8}$  in. round, and a much higher stress in smaller sizes.

Hard-drawn wire is a material of about 0.30 per cent carbon, which has not been annealed after the last few passes through the wire-drawing dies. It is not tempered either before or after winding. This at first sight would appear to be a very low grade material for spring making, but as a matter of fact it produces very satisfactory springs if the stress required is not too high. It is rather apt to be non-uniform, a condition which I have been told is usually due to failure to replace the wire-drawing dies as they become worn.

Another grade of spring which used to be common was bessemer wire, used for making cheap furniture springs. I know about this material only from hearsay, as there never was a pound of it in any shop with which I was connected. I believe it is now going out of use.

In addition to these carbon wire grades and one or two others which are used for special purposes, chromium-vanadium and silico-manganese steels in the usual wire spring sizes can be wound cold, and in sizes around No. 15 and smaller can usually be wound after tempering. These alloy steels, when intended for manufacturing into wire springs, should be electric furnace or crucible products.

#### TORSIONAL THEORY OF COIL SPRINGS

Next I want to say a few words about coil spring design, and will first point out that with experience and attention to detail it is possible to obtain very accurate results from the application of coil spring theory to practice; much more so than in the case of elliptics. The stress is considered as pure torsion, the small transverse load component being neglected. For compression springs of round bars the formulæ are:

$$(1) \quad \text{Load} = P = \frac{S \cdot d^3}{8M} \quad \text{and}$$

$$(2) \quad \text{Deflection per coil} = \Delta = \frac{8PM'}{Gd^4}$$

Substituting the formula for P in the deflection formula, we have:

$$(3) \quad \Delta = \frac{S \cdot M'}{Gd}$$

S is the torsional stress produced in the outer fibers of the section by the load P. M is the mean or pitch diameter of the helix, d is the diameter of bar, and G is the torsional or shear modulus.

Then if the stress S is taken as the maximum allowable for the material, formula 3 will state the maximum value of  $\Delta$  for the dimensions examined; further,

if the spring is to be capable of testing solid (coil to coil), the value of  $\Delta$  from formula 3 will also be the "maximum allowable space" or opening between adjacent turns of the spring.

Likewise, formula 1 will give the load carried by the spring when coil to coil; or, as it is usually called, the "capacity" of the spring. The total movement of the spring is the space between turns times the number of active turns. The tapered ends of the spring, being dressed down flat, have no movement, and must not be counted as active turns. Many spring designers overlook this point and get into trouble. There is a wide difference of opinion among authorities as to the proper values for  $S$  and  $G$ . About this more in a moment.

The formulæ for coils of square and rectangular sections, as given in most of the text books, are fundamentally wrong. They are based on the assumption that these sections retain their shape under torsional stress; whereas you can see in an instant, by twisting an ordinary rubber eraser, that the section becomes warped. The true theory was announced by St. Venant, the French mathematician, who worked out the formulæ for a rectangular section (of which the square is a special case) and for the triangle and ellipse. The problem is a very pretty one in the Theory of Elasticity. It is set forth more or less fully in several English works—I think that of Prof. Burr of Rensselaer Polytechnic is the most complete. The equation for rectangular sections involve infinite series of hyperbolic functions, and are difficult to turn into usable shape. But to illustrate the error in the old formulæ, these give for square sections:

$$P = 0.4714 \frac{Sd^3}{M}; \text{ and } \Delta = 4.712 \frac{PM^3}{Gd^4};$$

whereas the correct values are:

$$P = 0.4161 \frac{Sd^3}{M}; \text{ and } \Delta = 5.58 \frac{PM^3}{Gd^4}.$$

An interesting result of the St. Venant torsion theory is that the points of maximum stress in a rectangular section are the middle points of the long sides—in other words, the points on the periphery nearest the neutral axis; whereas the old theory assumed that the maximum stress occurred at the points furthest from the neutral axis, i.e., at the corners.

#### EFFECT OF OVERSTRAIN ON ELASTIC LIMIT AND SHEARING MODULUS

A few curious things have been developed by research work on coil springs. In the first place it must be explained that in hot-coiled work it is customary to wind a spring so that it will have a free height considerably higher than the free height specified for the finished spring, this excess free height being removed as "permanent set" in the solid test. In railroad springs the excess free height is from 25 per cent to 100 per cent of the total movement of the spring after the excess height has been removed by the solid test. The average figure is about 50 per cent. The result of this practice is to increase materially the capacity and total movement of the spring. Take as a concrete example the outside coil of a Pennsylvania Railroad class H-24 spring, the dimensions of which are:

Outside diameter = 6½ in.  
Free height (final) = 8 in.  
Size of round bar = 1½ in.

If this spring were wound 8 in. high, it would test down to about 7¾ in. Other results would be about as follows:

| Free Height As Wound. | Free Height After Test. |
|-----------------------|-------------------------|
| 7½ in.                | 7½ in.                  |
| 8 in.                 | 7½ in.                  |
| 8½ in.                | 7½ in.                  |
| 8¾ in.                | 8 in.                   |
| 10 in.                | 8½ in.                  |

By winding the spring 11 in. high, we could perhaps gain another ½ in. in final free height, but the springs would probably be crooked after testing.

At the same time, an increase in winding height gives an increase in the capacity of the spring, but the increase in capacity is not as great proportionally as the increase in final free height. Thus we have increased the apparent elastic limit of the material. What has actually happened is this:

Let Fig. 2 represent the end view of a round bar fixed in a torsion machine, and let the line  $OA$  represent two radial elements in the same longitudinal plane and at opposite ends of the bar. Now suppose one end of the bar twisted so that the element  $OA$  at that end takes the position  $OB$ , the other end of the bar being fixed. Assume that the peripheral distance  $AB$  exactly corresponds to the shearing strain in the material when stressed to the elastic limit. Then the element  $OB$  will return to the position  $OA$  when released, as none of the fibers have been

stressed beyond the elastic limit. But suppose the bar twisted until  $OA$  takes up a position  $OC$  beyond  $OB$ , and fix a point  $D$  which is twisted around to  $E$ , the curved distance  $DE$  being equal to  $AB$ . Then all fibers between  $E$  and  $C$  have been stressed beyond the elastic limit,

and tend to take permanent set; while the fibers between  $O$  and  $E$  have not passed the elastic limit, and tend to return to a position  $ODF$  on release.

But in attempting to take up this position, the fibers between  $D$  and  $F$  are sheared past each other. This shear is entirely distinct from the shear between adjacent cross-sections, which is the only one considered in the usual torsion theory. As a matter of fact, these two shears—the one between adjacent sections attempting to maintain the element in its position  $ODF$  and the other between adjacent fibers of the same section and tending to return the element to its original position  $ODA$ —are opposed to each other. The element will then come to equilibrium in some hypothetical position  $OH$ . In other words, we have raised the apparent elastic strain limit of the bar in the ratio of  $AB$  to  $HC$ .

I have never attempted to construct a mathematical formula defining the position  $OH$ . It is not strictly a

FIG. 2. ROUND BAR IN TORSION

mathematical problem, as we must know first the exact position of  $F$  in terms of  $AB$  and  $AC$ , which in turn involves the behavior of the material under stresses exceeding the elastic limit.

Now you can see what has happened to the H-24 spring, when tested down from an original height of 9 or 10 in. If wound to a height of  $7\frac{1}{2}$  in. the true elastic limit would not be exceeded and the spring would not lose any height in testing. If wound 9 in. high, it took a set, but the "apparent" elastic limit and the free height were considerably increased over that of the spring wound at  $7\frac{1}{2}$  in. as a result of the application of overstrains.

As soon as I got to work in the laboratory on this "theory of overstrains," I discovered some curious facts. In the first place, they reduce the life of the spring. An H-24 spring wound  $7\frac{1}{2}$  in. high will stand so many thousand solid tests before failure. If wound 9 in. high it will survive only about one-half as many solid tests; and if wound 10 in. high, only about one-quarter to one-third as many. Again, the raising of the apparent elastic limit by overstrains carries with it a reduction in the apparent shearing modulus. The diagram explains this at once; the modulus is a stress by strain ratio, the stress used being that in the outer fiber, and the ratio remains constant only so long as the original radial elements remain radial. This is the reason why you will find so many different values given in the text books for the shearing modulus as applied to steel coil springs. One will tell you it is 12,500,000, another 11,500,000, still another 10,500,000. As a matter of fact, the true modulus is 12,000,000 to 12,500,000; the apparent modulus may run down to less than 10,000,000 in a spring which is wound very high. In designing or checking a design, the apparent modulus has to be chosen with very careful regard to the height at which the spring is wound.

#### MOLECULAR HYSTERESIS IN OVERSTRAINED COILS

It is almost universal practice to make load tests of coil springs on "compression"—that is, going down from free height to solid height. But a few years ago the Navy Department decided that it would be well to have their springs tested on "release," i.e., coming up from solid to free. It immediately developed that the loaded height of most coil springs under any assigned load, if taken on release, was less than if taken on compression. A similar phenomenon is found in testing elliptics, but here the difference between the tests is obviously due to friction between the plates of the spring, which of course have to slide over each other when the spring is deflected. Some one then conceived the idea that in the case of coils the difference between tests was due to friction between the bearing surfaces of the spring and the plates of the testing machine, since a coil spring winds up slightly when it is compressed. So we rigged up a ball-bearing device to remove this friction, but it did not have any appreciable effect.

Then an investigation soon found that this difference between release and compression tests was related to my theory of overstrains. If the true elastic limit of the metal has not been exceeded in the original solid tests, there is substantially no difference between release- and compression-load tests. With increase in overstrain the difference in question increases rapidly, until with a

rather excessive overstrain it is about 25 per cent of the deflection of the spring under an average load. The explanation of the difference remains a mystery, but evidently there is a mechanical hysteresis present in overstrained coil springs.

That the phenomenon is due to some internal condition of the metal is indicated by the fact that we can wipe out a considerable proportion of the difference between tests by giving the spring a second draw after testing it solid at a somewhat lower temperature than the original draw. I stumbled on this fact by accident, and then made a complete series of experiments on it. The results obtained by this second draw are somewhat erratic, but one can always increase the height for a given load on release-test perceptibly, and usually the gain is about 50 per cent of the difference between tests when the spring is not given the second draw. Strangely enough, this expedient does not affect the compression test to any great extent, but only the release test.

Finally, I would like to mention an interesting verification of the theory of overstrains. It has been pointed out in connection with the St. Venant theory for rectangular bars in torsion, that the points of maximum stress are the middle points of the long sides. Evidently, then, when overstrains are applied to a spring made of square or rectangular bar, the proportion of the section which is overstrained a given amount is much less than in a round bar spring. We should therefore expect the elevation of apparent elastic limit to be more marked in square bar springs than in rounds. This is exactly the case. For rounds of  $\frac{1}{2}$  in. to 1 in. bar, the apparent elastic limit after large overstrains would run about 110,000 to 120,000 lb. per sq.in. for commercial work; whereas in squares of the same sizes and under the same conditions we could get 130,000 to 140,000 lb. per sq.in., and with rectangular bars of wide, thin section some almost fantastic figures can be obtained.

There is practically nothing about overstrains in text books as regards either springs or any other branch of mechanical theory. Certainly our knowledge of the fundamental truths underlying the Strength of Materials Theory is in a state far from satisfactory. My own idea is that the problem will be found to be a molecular or an atomic one, and chemists and physicists will have to come to the rescue. The man who writes the "Mechanics of a Molecule" or the "Mechanics of an Electron" will throw a flood of light into many dark corners of engineering theory into which we have to venture every day.

Crucible Steel Co. of America,  
Pittsburgh, Pa.

#### Licenses to Enemy Patents

The I. E. du Pont de Nemours & Co. of Wilmington, Del., filed application on Nov. 22 for the use of German owned U. S. patent rights on the following:

"Producing Ice Colors," "Stable Indigo-White and Process of Making Same," "Compounds of Leuco Vat Dyes With Aralkyl Compounds and Process of Making Same," "Reducing Indigo Coloring-Matters," "Aromatic Ammonium Compounds and Process of Making Same," "Azo Dyes from the Arylamids of 2,3-Oxynaphthoic Acid and Process of Making Them," and "Condensation Products from the Arylamids of 2,3-Oxynaphthoic Acid and Formaldehyde and Azo Dyestuffs Therefrom and Process of Making Same."

## Refractory Products\*

BY A. MALINOVSKY

REFRACTORY ware may be satisfactory in one furnace under one set of conditions, whereas it may not meet the requirements in another furnace with different substances and under a different set of conditions. Today many types of refractory materials are on the market in the form of bricks, crucibles, etc., which are manufactured from different substances for different purposes as required in various lines of industries. These refractory wares must resist different heights of temperature, depending upon the particular use to which they are put.

It has been demonstrated by different authors that some refractory wares will melt and frequently volatilize at heats where others remain intact, due to certain conditions existing within the furnace. Some refractories carry a load when exposed to a high heat at which others collapse. The success of refractories in operations where high temperatures are employed and the economical advantages to be derived from them are so intimately connected with the material employed in building crucibles or furnaces that it is important to know how to select a material possessing the properties which will enable it to withstand the required conditions. It is particularly difficult to obtain a material which will serve satisfactorily under conditions in which high temperatures are combined with the action of acid fumes, or alkalies, which act as a flux and produce chemical reactions tending to lower the refractory properties of the ware.

Refractories that are high in silica will carry loads at high temperatures satisfactorily, but are particularly susceptible to the combined action of heat and certain acids, alkalies or slags. A fire clay ware containing a high percentage of free silica, when it comes in contact with substances containing fixed bases, suffers a deterioration in its refractory properties, owing to the fact that bases will combine with free silica and will form fusible silicates at low temperature. The chemical effect of substances containing low fusible oxides of metals upon refractory ware, such as glass pots, crucibles or other utensils, is not always readily detectible and is due largely to the action of salt vapors and flue ashes.

Refractories should be composed of materials burned at high temperatures which are strong enough, when molded into ware, to hold at a high heat their contents and weights without distortion. A first class fire brick should carry a load of about fifty pounds to one square inch at 1350 deg. C. It is important for fire brick, especially, to reach their greatest degree of hardness and to contract to their full extent before they are used in a furnace.

The degree of fusibility of a refractory ware depends upon its chemical characteristics, its elementary composition and texture and its physical properties. In other words, fusibility is not only influenced by the elements which enter into the combination of the substances and the proportion in which they are combined, but also by the properties of the compounds or mixtures of various minerals. It appears that the property of

easy fusibility in refractory material depends, first, upon the nature of the complex compound bases such as the alkaline earths and the oxides of metals; second, upon the proportion which exists between silica and alumina; third, upon the shape and fineness of the grains; and, fourth, upon the physico-chemical changes which take place when the material is under fire.

It is well known that the alumina is the clay base which forms one of the most highly refractory materials when the content present is high enough to resist slagging and heat actions. It is such material that is extensively used for commercial and technical purposes. The refractory quality of fire clays is increased by the addition of finely ground bauxite or flint clay. It must be understood that not all bauxites and not all flint clays are suitable. Pure materials must be had and they are of limited quantity.

Refractories may be divided into three different classes, acidic, basic and neutral. I think that purely acidic or basic conditions very seldom exist in a furnace, if ever at all. Acidic refractories are made from pure quartz known as ganister, or quartzite. As silica possesses no plasticity, it has no binding property. Some manufacturers use clay as a binder, though it is not a very satisfactory binder for silica brick. The colloidal clay shrinks enormously upon heating and the silica expands considerably. When the brick is reheated, the silica will continue to expand and the clay to contract. These two physical properties work contrary to each other, producing a porous, ware having a very weak and loose structure.

The best results are obtained with lime, which is used the most at present. From 1 to 2 per cent of lime is added in the form of milk of lime. Mixed with the finer silica particles, it envelops the coarser silica grains and at high heat sinters the grains together into a strong body in the form of a net-like structure through the mass. Some authors state that the flux forms calcium monosilicate,  $\text{CaSiO}_3$ , which is known as wollastonite. However, the writer believes that there must be different calcium silicates present in the magmatic solution of a silica product. The best results in the manufacture of silica brick are obtained by heating the brick to cone 20, at which temperature the greatest part of the silica is converted to cristobalite and tridymite. It can be said that nearly all the fire clays are acidic, as the silica is dominant in nearly all of them.

Basic refractories consist of magnesite, dolomite and limestone. Limestone has high refractory properties, not being fused or softened (except in the electric furnace), but on account of the properties it possesses, in that the calcium oxide readily reacts with  $\text{CO}_2$  to form calcium carbonate and crumbles, it has never come into great commercial use. Dolomite is calcined, ground and mixed with tar, molded under pressure and heated to a high temperature. The calcined dolomite is also mixed with slag and used in the open hearth furnace, by merely throwing it into the furnace with a shovel, to protect the walls of the furnace.

Magnesite requires a greater heat for calcining than limestone or dolomite to expel all the carbon dioxide and is usually exposed to white heat. After cooling it is ground and mixed with a low calcined magnesite or some other binder and then molded into brick under enormous pressure with a hydraulic press and heated

\*A paper read at the meeting of the American Chemical Society, St. Louis, Jan. 7, 1918.

to a very intense heat. Magnesite is very refractory and resists metallic action, but fuses readily in contact with silica. The same is true of limestone or dolomite. Magnesite is a good heat conductor and is for this reason very suitable for metallurgical work as well as for the lining of electric furnaces. Magnesite brick under load at high heat will collapse. When exposed to sudden changes of temperature, it spalls very badly on account of its density and friability.

Neutral refractories are those which resist silica and basic oxides. Graphite, chrome and some bauxite with pure fire clay mixtures are representative of these. Bauxite in its raw composition is a hydrated alumina, containing a varying proportion of impurities, as silica and iron. On heating, the water is driven off and the impurities, as silica and iron, increase in quantity, which tends to nullify the refractory quality of bauxite. The content of water varies from 6 per cent to 34 per cent and that of iron from 1.5 per cent to 30 per cent. Bauxite before it is used must be calcined at a very high heat, from 1200 deg. C. to 1350 deg. C., and again must be repeatedly heated before all the contraction has been obtained. Carbon refractories are made by mixing graphite or charcoal or coke with a good plastic fire clay and burning at a high heat. Oxidizing conditions must be avoided when carbon ware is burned.

Chrome brick, made of chrome iron ore, is a very valuable refractory, as it has the property of resisting both acid and basic slags. Therefore, it is used in furnaces as a neutral lining between acidic and basic refractories. The writer has had experience in open hearth furnaces where silica bricks were placed directly upon magnesite bricks. Where the two different refractories come in contact with each other, a protective layer of calcined dolomite from 12 to 18 inches thick is placed so that the heat cannot be raised to flux them. Chrome brick is very valuable in repairing furnaces when they are under a high heat, as it resists sudden changes of temperature, but will fail and give way at high temperature under high loads the same as magnesite.

Refractories are also made from rare minerals containing zirconium, thorium, yttrium and beryllium oxides. Among these zirconia is the most developed for refractories, as it has a very high melting point, nearly 2000 deg. C., and resists all acid and basic slags. Its heat conductivity is very low. Zirconia is produced from the mineral known as baddeleyite from Brazil.

A very important factor which must not be overlooked is the mortar in which the bricks are laid. Refractory bricks made from fire clay should be laid with the same clay the bricks are made of, mixed with fine ground brick or grog to decrease the contraction. The mortar for laying silica brick should be very high in silica and low in alumina and other impurities as iron, lime, etc. Magnesite brick should be laid with magnesite mortar or with dry magnesite powder.

Care should be taken when building furnaces to select the right kind of material and mortars, especially in open hearth regenerators, blast furnaces, cupolas and coke ovens, where the mortar may give away and the strong draft deposit the destructive cinder slags in the joints, where they accumulate and, acting as a flux, fuse large cavities in the brick, thus weakening the whole structure. Therefore, if we test the refractory ware

against cones, we should test the mortar at the same time, as it should be borne in mind that a high aluminous mortar for silica brick will act as a flux and slag the brick. The alumina content should be by no means greater than 10 per cent. We also have to keep in mind that refractories with a close texture and fine grain will the better resist abrasion, attack of fluxes, fumes, vapors, slags, flue dust, etc. Refractories with open structure and coarse grain will best stand sudden changes of temperature, but will disintegrate very quickly in contact with salt fumes, slag, flue dust, etc.

As seen from the foregoing, texture is a very vital point. It is well to know where and in which part of the furnace it is most suitable to use brick with a close texture.

I believe that if all engineers, chemists, metallurgists or any firm using ceramic wares would join the American Ceramic Society, many of the defects of present ceramic wares could be eliminated. The society will be of great value with its membership of trained technical and practical men who are capable of solving the difficulties which confront those engaged in any line of industry using fire brick or stone ware. Many firms believe that any college-trained chemical student who is able to make an analysis of clay should be capable to work out ceramic problems. Technical men with a chemical and scientific education will be lost in ceramics until they have had practical experience. It is a great mistake to employ students (as I have seen in most iron and steel works) with the expectation that they are equipped to work out ceramic problems.

It is beyond the ability of the average chemist to conduct a proper analysis of a clay. An analysis of such complex substances as clay, or any other ceramic material, should be made by experienced ceramic chemists. We should welcome heartily the wider knowledge and the progress in ceramics which will attend the growth of the American Ceramic Society.

Lincoln, Ill.

### To Expedite Demobilization of Soldier Chemists

As hostilities cease we naturally must again turn to peace-time conditions and look forward to the future development of chemical industry in America. The problem now before the Industrial Relations Branch of the Chemical Warfare Service is to assist chemists in service to secure positions where their training and experience can be used to the best interests of the Government. This enormous readjustment is rendered possible through the information gathered by Dr. Charles L. Parsons, secretary of the American Chemical Society, and through the questionnaires sent out by Major F. E. Breithut of the Personnel Division of the Chemical Warfare Service.

To accomplish results chemists now in military service who desire to return to chemical industry are being requested to inform the chief of the Industrial Relations Branch concerning their future prospects, and manufacturers are being asked to designate their requirements for chemists. The administration of this work will be carried out by the Industrial Relations Branch and information may be obtained by writing to Major Allen Rogers, Chief, Industrial Relations Branch, Chemical Warfare Service, 7th and B Streets, N. W., Washington, D. C.

## Quicksilver Operations at Monte Amiata, Italy

The Italian Deposits Were Opened in the Twelfth Century, but Were Dormant After the Crusades Until 1860—Most Important Operations at Present Are at Siele and Abbazia San Salvatore—Preparation of Ore Furnaces in Use

BY DR. ROLAND STERNER-RAINER<sup>1</sup>

**D**ISCOVERIES of stone hammers, arrowheads, wooden plates and coins made upon opening the old workings around Monte Amiata show that these mines were worked for cinnabar by the Etruscans and later by the Greeks and Romans. (These relics are preserved in two small museums by the managements of Siele and Cornacchino.) At Morone some mining was carried on in the twelfth and thirteenth centuries. War and pestilence closed the mines and they were reopened only in the middle of the last century. They gained importance but slowly because of the tremendous production of California. From 1860 to 1874 only the Siele works were in operation. One year later the Solforate Schwarsenberg began producing in a small plant which was closed in 1885. Cornacchino produced in 1880, and in 1887 Reto or Monte Buono followed suit. Twelve years later the plant of Abbazia San Salvatore was opened and in the following year took over the abandoned Corte Vecchia. In 1906 the Siele plant opened the deposits of Solforate Roselli, in 1908 those of Petrineri, near Bagni San Filippo, and in 1909 those of Morone, near Selvena.

### SITUATION OF WORKINGS

At present the district of Monte Amiata embraces seven plants belonging to five companies, and the Cerreto Piano property at Pereta is being developed.<sup>2</sup> The new "Merkur" company, financed by the banking interests of Bleichröder, of Berlin, have been endeavoring for the past year to prove the extension of the old ore body in the trachyte district south of Abbazia San Salvatore. These efforts, though extensive, have been unsuccessful so far.

None of the plants is situated on a railroad. The nearest railroad point is Monte Amiata, on the line Grosseto-Asciano-Siena, from where the 20-kilometer mountain road leads to Santa Fiora, picturesquely situated on the banks of a stream of the same name which flows along the southern slope of Monte Amiata. After covering an additional 15 kilometers, Abbazia San Salvatore, Siele, Catellazzara and Cornacchino are reached. A second railroad point is Chiusi, on the Rome-Florence Railroad, from where a 40-kilometer road leads through vineyard and chestnut groves to the various plants.

The most important deposit is that of Abbazia San Salvatore, situated on the east slope of Monte Amiata,

a well-wooded mountain of 1734 meters elevation. The deposits lie in a north and south direction, as do those of the other properties. The mineralized zone<sup>3</sup> is found in the lower Jurassic, the Eocene and the Pliocene sandstones. It has been found that the ores are richer and more abundant the more argillaceous the limestone and the nearer to Monte Amiata. Since the ore is horizontally disposed and outcrops at many points, meteoric waters "filter" into the mines, giving rise by chemical reactions to a strong evolution of carbon dioxide and hydrogen sulphide gas. Excepting the two most northerly mines, Abbazia San Salvatore and Petrineri, all of the mines suffer to a greater or less extent from this evolution of gas.

### SAN SALVATORE MOST IMPORTANT

In the beginning of the '80s the German geologist Dr. Schwartzberg studied the region about Monte Amiata, and finding cinnabar in the creek gravel of San Salvatore, acquired property in the neighborhood for mining purposes. For several years an open cut was worked, when the dwindling ore reserves necessitated deep mining. In a short time the primary ore body was located. The geology has not been completely worked out, but new light will probably be thrown on the geological relations when this ore body has been opened on deeper levels. Ever since then the mine has grown in importance and has long been the most important of the district, producing 20,200 flasks of quicksilver in the last year, as against 19,880 flasks of the previous year.

The faces of drifts and crosscuts are sampled before stopping is begun, as the clay often hides the cinnabar, making it difficult to judge the ore by eye. Besides this average ore, which constitutes the greater tonnage mined, a rich shoot of 30 per cent ore is being stoped. Despite the enormously greater tonnage of average ore, one-fourth of the mercury production is derived from the high-grade ore. Rich pockets are worked individually. The ore is hand-sorted underground and premiums are given to the miners to insure their interest in the sorting process. The minimum content of the sorted ore is placed at 12 per cent, while the average content is around 18 or 20 per cent. This ore is trammed to drying floors and furnaced separately, as it is believed that longer roasting is necessary for higher grade ores. All ores are trammed to the "deposito," on a centrally located tramping level; the ore is lowered to the tram

<sup>1</sup>A portion of a paper on "The Present Status of Quicksilver Metallurgy in Europe," translated by C. N. Schuette from *Osterreichische Zeitschrift für Berg- und Hüttenwesen*, Vol. 62, 1914, p. 529. The translation was made in connection with a coöperative investigation of the metallurgy of mercury being carried on by the Bureau of Mines and the New Idria Quicksilver Mining Co., and published by their courtesy.

level through offset chutes and is hoisted from the lower levels.

At the reduction plant the ore is dumped on a grizzly of 80 x 100-mm. mesh. The wall rock is hand-spalled and does not have to be dried before being charged to the shaft furnaces. The material that passes the grizzly is fed into the rotary drier, shown in cross-section in Fig. 1, and in perspective in Fig. 2. The temperature in the cylinder is never more than 150 deg. C. The drying gases (generated by burning

FIG. 1. CROSS-SECTION OF ROTARY DRIER

brush) pass through the drier in the same direction as the ore, and at first contact with the wet ore they are cooled to such an extent that quicksilver losses are not to be feared. A thermometer inserted into the overlapping casing indicates the temperature fluctuation. Screens are fitted to the end of the drum which classify the dried ore into plus and minus 40-mm. sizes. The coarse ore, a hard limestone with a 0.4 per cent mercury content, always equals just one-half of the fines; the fine ore, a mixture of argillaceous dust, clay nodules and shattered limestone, has a content of 0.9 to 1 per cent mercury. The capacity of the drier is 7 tons per hour, the moisture content of the ore being reduced from 15 to 4 per cent. Four men work on the grizzly; one man fires the drier, and two men draw the dried material. A total of 32 men is needed to dress the ore.

#### DUST COLLECTED AND SAVED

The moist, dust-laden drier gases pass into a settling chamber where most of the dust is recovered. The last remnants of dust are arrested by a water spray in a second chamber, after which the gases escape. The collected dust is loaded into cars with a belt conveyor and is taken to a wet dressing plant, which seems justified, as this dust would otherwise go to waste. Thirty tons of dust per month are concentrated to a slime carrying 40 to 50 per cent mercury. This slime is treated in two Ferraris furnaces (a hand reverberatory with inclined hearth) and recovers 24

flasks of mercury. The loss in concentration is estimated to be 12 to 16 per cent. It is planned to burn this dust together with all minus 5-mm. material in a rotary kiln furnace built in a manner similar to the rotary drier. From this kiln the gas will pass into a settling chamber, and from this settling chamber will rise the pipes leading to the condensers. If the trials prove successful, several of these kilns will be erected.

The high grade ore and the wet concentrate are dried on drying floors. This was the original method of drying all ores. As was common in the district, the ore was air-dried under roofs, sun-dried and later, with increasing production, the ore was dried on a sheet iron floor, heated from beneath by the hot gases from a grate fire. Since excessive drying caused mercury losses and as the handling of the ore was not only costly and time-consuming but also unhealthful, the former director, F. Ammann, built a "shaft-drier" as far back as 1903. The ore was charged at the top and descended over a zigzag of iron plates. Each knee contained a slit, allowing the moisture to escape into the drying gases. Ammann also originated the four "drying canals," which are not in operation at present, being kept in reserve. These drying canals are heated tunnels, 1.3 x 1.4 meters in cross-section, and 80 meters long, the ore losing its moisture when run through this tunnel on cars having perforated sheet-iron bottoms.

The dried ore is sampled before further treatment. The run-of-mine ores are sampled several times monthly for rough control. The gold cover assay method was used. The pulverized ore is mixed with a small quantity of granulated copper, and heated in a crucible. A half-gram sample suffices for high-grade ore, one to two grams are taken for low-grade ore, while 0.2 gram is

FIG. 2. ROTARY DRIER IN OPERATION

sufficient for pressed soot. The average assay value of the ore treated is 0.8 per cent mercury.

#### FURNACE PRACTICE AT ABBADIA SAN SALVATORE

At present the plant consists of 14 Spirek shaft furnaces and 6 Cermak-Spirek fine-ore furnaces. The shaft furnaces, Fig. 3, are of identical construction, the

<sup>1</sup>From a letter from Director Trögel, Abbadia San Salvatore, we hear that the kiln has been in experimental operation for two months and that the results have led to several modifications of the plant. When these have been tested—say in the first part of 1914—it will be decided whether this kiln shall be duplicated or whether the Cermak-Spirek furnaces shall be equipped with producer-gas firing, as has been done in Idria. For notes on the use of a rotary kiln at New Idria, Calif., see *Chemical & Metallurgical Engineering*, Vol. 19, p. 239 (Sept. 1, 1918).

circular shaft, 1 meter in diameter, being built of local trachyte. Each has a capacity of 7 tons per 24 hours, 1.5 per cent of charcoal being added to the charge for fuel. An automatic feeding device of local construction insures a fumeless charge-hole.

Four of the fine-ore furnaces which together treat 10 per cent of the ore have a capacity of 25 tons, and two have a capacity of 12 tons per 24 hours. The cinnabar concentrates and the pressed soot are furnaceed with the hand-sorted high-grade ore, these charges being more carefully controlled and burned twice as long as low-grade ore. Sluicing of tailings at two-hour intervals is customary in the district by using creek water flowing under the draw doors of the fine-ore furnaces. Only the coarse ore tailings are carried to a dump which has so nearly reached its maximum size that it is proposed to utilize these tailings to fill the mine workings.

Sixty men are necessary to operate the furnaces, the wages ranging from 3.10 to 3.80 lira.<sup>a</sup> The wood is supplied by 18 men.

All furnaces are equipped with Cermak condensers, the parts of which are made by a clever potter of Castellazzara, who furnishes these pipes even to American plants. The soot boxes are arranged, as is customary, perpendicular to the line of the condensers, allowing the first inverted U-pipe to be cleaned every month, while the others are cleaned only at the main clean-ups. All soot found in the system on the furnace

sary draft, while one is kept in reserve. With a consumption of 7.7 horsepower, a rotor diameter of 800 mm. and a speed of nearly 1000 r.p.m., they move 212 cu.m. of air at 21 deg. C.

It may be mentioned that an attempt was made at this plant to shorten the time of bottling the product by measuring the volume instead of weighing the mercury. (Fig. 5.) For this purpose Director Ammann

FIG. 4. STONEWARE EXHAUST VENTILATORS

constructed a suitable apparatus and designed curves, giving the volume of various temperatures. This method, however, could not replace the apparently tedious weighing process, because the small gain in time was offset by the inaccuracy caused by the unavoidable temperature variations during the manipulation.

Losses do not worry the management at Abbadia San Salvatore; in fact, the output of mercury is greater than the indicated ore content obtained from the sampling and assaying. It is not possible to say where the error is made without an intimate knowledge of the method of calculating the input. Considering the clean and careful operation of the plant, one would probably not be far wrong in placing the loss at 9 per cent, the figure obtaining at Idria, with which plant it can most readily be compared both as regards ore content and scale of operations.

#### OPERATIONS AT SIELE

Siele is the second largest producer, with 150 tons of mercury per annum. The ore body is exploited through the mine in the valley of Siele and through the younger Solforate Roselli mine, which lies across the watershed on the drainage basin of the Fiora. The Siele deposits are nearly exhausted, and in a few years the Solforate will probably furnish the entire ore, which is transported to the reduction plant by a cable tramway. In Siele itself the neighboring property is in other hands, which, according to the Italian mining law, is a bar to further development. These ores, in argillaceous limestones of the upper Eocene, are richer than at any other mine in the district, as this crumbly material was most favorable for the deposition of cinnabar. Even though the average ore content is more than 2 per cent mercury, richer ores than these impregnations are found only in small quantities, and it is necessary to sample the ore in place to determine its content, since the cinnabar color is almost completely hidden by the rock. The moisture content is 20 to

FIG. 3. SHAFT FURNACE AT ABBADIA SAN SALVATORE

side of the exhauster is treated in Exeli soot presses, the mercury content being reduced from 50 to 15 or 20 per cent. The plant has three stoneware exhausters, Fig. 4, installed by the Ton- und Steinzeugwerke of Berlin-Charlottenburg. Two of these induce the neces-

<sup>a</sup>A lira is equal to \$0.193.

25 per cent, as this is one of the wettest mines. This is also the reason for the gas exhalations and the absence of gypsum, which, excepting for a few small crystals, appears to have been leached away.

After the ore has been dried on drying floors it is passed through two crushers, as the entire tonnage is treated in fine-ore furnaces at present. A 24-ton, a 12-ton and a 3-ton furnace (which burns the pressed soot and the very high-grade ore) suffice to treat the entire present tonnage. The 24-ton furnace treats only 18 tons per day, as the high percentage of fines necessitates a 30-mm. interval between tiles. The 12-ton furnaces, however, can treat 13 tons in 24 hours, as the heating flame penetrates the flues more readily. The disposal of the tailings is also accomplished by means of creek water. The furnaces are cleaned monthly, and the soot of the small furnace treating the rich product is gathered every two weeks. An electrically driven soot mill and the two storage pots equipped with siphons

FIG. 5. AMMANN'S MEASURING DEVICE

complete the equipment of this little plant. Formerly, when the dried concentrate was treated in retorts (of which two or three were combined into one branch), the losses were high, but they are today estimated at 5 per cent of the input. The cost per flask of metal is 140 to 145 lira (\$27 to \$28).

#### CONDITIONS AT CORNACCHINO

Mining conditions at Cornacchino are even less favorable. Cornacchino is situated near the village of Castellazzara in the drainage basin of the Paglia (Tiber), near the intersection of the provinces of Grosseto, Rome and Siena. The mine belongs to "Eredi Schwarzenberg," as does a mine situated some distance to the west across the hills, near ruins of Castle Roccaccia. Both of these mines have their own reduction plant. The ores of Cornacchino are siliceous schists impregnated with cinnabar. The original ore body, which was in limestone, had very much richer ore than those mined today, but it has been completely worked out.

During the '80s these ores were burned in shaft furnaces and retorts. It was only when the Cermak-Spirek furnaces became known that the porous and fragile cinnabar bearing siliceous schists of the foot wall could be treated economically. The treatment of such fine ores in retorts or reverberatory furnaces

seemed economically impracticable with metal contents as low as 0.35 to 0.4 per cent.

The ore as mined is fairly dry and no artificial drying is needed, as is necessary at most of the other plants. The coarse ore amounts to about one-fifth of the fine ore, so that at present one 24-ton fine-ore furnace and one shaft furnace are used; the latter, however, is in intermittent operation through lack of coarse ore. The developed ore reserves insure a ten-year life of the mine at the present rate of production. The plant can continue operation only if new ore bodies are developed and if wages and the price of wood do not increase further.

The process of dressing the ores which contain 7 to 8 per cent moisture consists of screening them into plus and minus 40-mm. sizes. The minus 40-mm. material contains 0.35 per cent mercury, and the plus 40-mm. material contains but 0.05 per cent mercury. A sample is taken from each car of the screened material as it is brought to the furnace. A twenty-four-hour sample is crushed and assayed for mercury and moisture. Seven to eight grams are used for an assay, which is prepared with zinc oxide and hammerscale, as at Idria. The shaft-furnace feed is not sampled. The burnt rock is sampled in the morning and in the evening just before ore is drawn in the fine-ore furnaces. About 20 grams of this are used for an assay. The shaft furnace soot is very rich despite the poor grade of the ore treated by these furnaces; the ratio of free mercury to mercury in the soot is 1 to 3, while at the fine-ore furnaces only 17 to 20 per cent is recovered as free mercury. The pressed soot from the shaft furnace still contains 28 to 50 per cent mercury. The plant (which is working with a loss of 15 to 20 per cent) produced 1200 flasks during 1912, including 2500 kg. of mercury from the shaft furnace. The cost of production was 150 lira (\$29.15) per flask. Sixty-eight men were employed in the mine and sixteen in the metallurgical plant.

#### MODERN SPIREK FURNACES AND CONDENSERS AT MORONE

The ore deposits of Morone lie in the nummulitic limestone and at the contact of limestone and shale. The ores, which average 1 per cent mercury, are therefore very argillaceous. Because of the great quantity of water which aids the rock disintegration, a considerable volume of gas is evolved. The run-of-mine ore contains between 15 and 20 per cent moisture.

Since this plant was erected only a few years ago, Spirek's successor, following the fundamental ideas of his uncle and teacher, was enabled to apply all of his experience in its construction. Since the method of operation of nearly all the quicksilver plants of Tuscany is based upon the experience of the two Spireks, it might not be out of place to discuss the results.

In the development and improvement of the fine-ore furnaces it became manifest that the 24-ton furnaces, which use 12 per cent by weight of the input of fuel, are economical where beachwood is available. Other varieties of wood, such as oak, chestnut or fir, are not as suitable for this size of furnace because of the shorter flame, which does not suffice to completely burn the ore. With the 6-ton furnaces the ratio of ore to fuel is the same. Even though they necessitate more labor as com-

pared with the larger furnaces, they are very popular for high-grade ore and pressed soot, as complete roasting is more readily obtainable in them. The 12-ton furnace burns only 10.2 per cent of any kind of wood; the roast is complete, so that it may be used to furnace all ores.

A coarser or granular feed allows the space between tiles to be a little larger than with the dusty feed, the flame can more easily penetrate the flues and, since the cinnabar on these ores is deposited superficially, it is more easily and completely sublimated; this allows 26 tons to be treated in the 24-ton furnace without increasing the loss. With dusty or argillaceous ores the space between tiles is only 35 mm. (Abbadia San Salvatore and Morone 35 mm., Siele 30). Since these latter ores are generally richer, the slightly lessened tonnage is not very noticeable. It would pay to determine the degree to which the roasting must be carried so that the value of mercury driven off at the last is still slightly greater than the amount of fuel needed to drive it off, as it is possible that in current practice at Monte Amiata too much time and heat are used to extract the last small quantities. The upper row of inclined plates in the furnace is made of cast iron; in Siele the second last row has also been made of cast iron to prevent damage when charging. These upper rows of tile serve to seal the furnace charge, preheat and dry the charged material and are not themselves heated. The two lower rows of tile serve to preheat the air for combustion, and are not heated either. With the 12-ton furnaces the draw doors are placed along the short side of the furnace with the fire box, so that the first row of tile will be more evenly heated, while with the 24-ton furnaces the draw doors are situated on the long side of the furnace. The exit pipe is made of cast iron 4.5 meters long, as is also the first descending leg of the condenser. The flange connections of these pipes, packed with asbestos and red lead, have proven superior to sleeve couplings.

#### CONDENSERS OF FURNACES

A 24-ton furnace has ten parallel condenser lines, a 12-ton furnace has five, and the small 6-ton furnace has three. The large furnace has two small, separate condensers to draw off the moisture and charge gases from the upper two rows of tile. The two smaller furnaces are built with one such separate condenser. Three wooden soot-boxes of cedar, into which the U-pipes of the condensers dip, are arranged perpendicularly to the direction of gas flow. More than three of these condenser units are not necessary; flues and chambers of a large cross section, which reduces the gas velocity, are more efficient for the collection of soot.

Up to a furnace capacity of 36 tons per day, one square meter of chamber cross-section is sufficient, while above this capacity it must be correspondingly enlarged. The necessary draft of about 5 mm. of water is obtained with a Root blower. If the last inverted U of a condenser line shows a slight pressure when the cover is removed, the draft is considered correct. One damper is situated just before the exhaust and regulates the entire gas stream.

<sup>\*</sup>(Translator's note) The tile referred to are the tile shaped like an inverted V of the Cermak-Spirek furnace, often referred to as "gable tile."

The first and second soot boxes are cleaned once a month, the third every three months; the cleaned mercury is drawn every fourteen days. The floor of the plant is cemented and has a network of gutters to catch any scattered mercury. Soot from different localities is pressed separately, as by doing this it is thought that a better extraction is obtained. The pressed soot retains about 15 to 20 per cent mercury. The soot from the hot part of the iron exit pipes is poor and so dry that water must be added to it so that the quicksilver can be pressed out. Soot from the first box contains 80 to 85 per cent mercury, soot from the second box about 70 per cent, and that from the third 45 per cent. In the first chamber the soot contains 30 per cent, and this soot is also sent to the soot press. Poorer soot is mixed an equal part of ore and charged again. One man can work out 30 flasks of quicksilver in an eight-hour shift. The empty bottles, which are numbered and weigh 4.5, 4.6 or 5.5, or a maximum of 6 kg., are weighed before filling, as is also the mercury; the filled bottles are again weighed.

The reduction plant of the Morone lies on a terraced slope about 500 meters from the adit mouth. In summer the ores are sun-dried, in winter they are dried on drying floors to a 4 per cent moisture content. The clay is cobbled from the limestone pieces, and the latter are hand-dressed to the desired size. The clay rock is fed into crushers, the product of which—ore containing 1 to 1.2 per cent mercury—goes without exception to two 12-ton fine-ore furnaces. The lump ore containing 0.3 per cent mercury is burned in two Spirek shaft furnaces, which are iron-sheathed, as was customary with the Caillaux furnaces in use forty years ago in this district. The work is carried on in three eight-hour shifts; two men per shift are needed to operate one fine-ore furnace and one shaft furnace. Since the material charged at this plant is fairly dusty, all three soot boxes are cleaned monthly, the first chamber being cleaned every three months. The mine employs 135 men, the metallurgical plant 45. The average monthly production of the last year was 200 flasks and this year has been increased to 350 flasks, so that the year 1913 may show a total production of 114 metric tons of mercury. In view of the high-grade ore the plant loss is estimated at only 10 per cent of the input.

#### SMALLER PLANTS IN TUSCANY

The plant at Bagni San Filippo, Petrineri, treats its ores which contain 0.4 to 0.5 per cent mercury in two 12-ton furnaces and one twin shaft furnace, after they have been dried from a high percentage of water, in a manner similar to that employed at Morone. Thus far the financial aspect of the venture, in which 110 workmen produce 60 flasks of quicksilver per month, was not very promising. Recently gas exhalations encountered in the mine give rise to the hope that the primary ore body, which has not thus far been located, will soon be encountered.

The smallest plant is that of the Monte Buono mine, which treats its ore in a 24-ton fine-ore furnace. The ore is a sandstone impregnated with cinnabar running 0.2 to 0.3 per cent mercury. It is sufficiently dried by handling, and being a somewhat decomposed rock, is crushed with wooden mallets. The soot is mixed with

lime and treated in retorts to prevent the formation of soot from the soot. During the summer, the plant, which otherwise produces 40 flasks per month, is closed because the 80 miners are really farmers and work on their farms during this time.

The occurrences of antimony-quicksilver ores of the Maremma grossetana, which extends from Selvena over San Martino and Capita in a southwest direction to the Tyrrhenian Ocean, are closely associated with the above cinnabar ore deposits. The mine of Selvena, which is producing black bituminous lower Jurassic limestones impregnated with cinnabar, antimony-glance and pyrite, has been abandoned. The ores of San Martino, a red-colored, brown iron ore impregnated with cinnabar, occurring in thin Eocene strata, impregnated with antimony-glance, have no commercial importance. The same is true of the old mine near Capita at Capalbio, the ore deposit of which lies in the Rhatkalk near the contact of the Eocene.

### Colloids and Flotation

United States Bureau of Mines Technical Paper 200, "Colloids and Flotation," shows the application of certain facts of colloidal chemistry and physics to practical flotation operations. Some of the unexplainable troubles in the flotation plant can probably be explained by the facts that have developed in the study of colloids. They draw attention to the fact that at times some sulphides are not wetted by water and under other conditions are wetted. The last case is, of course, an abnormal one, and when this condition obtains flotation is impossible. It can probably be explained by the phenomena of adsorption. The adsorption phenomena are an effect due to surface energy. Surface energy is a product of surface tension multiplied by area. Therefore, the adsorption phenomena are affected by any factor that tends to increase or reduce surface tension. The surface energy and adsorption effects for solids can only be proven by analogy of the action of liquids and gases.

Willard Gibbs developed a thermo-dynamical formula to show that adsorption is due to a concentration of molecules in the surface of solids or liquids and that it can be either positive or negative. Therefore any material that will give negative adsorption for water, say, would probably give positive adsorption for gases. Impurities in solution tend to upset surface energy conditions and would cause positive adsorption for gases to be changed to negative adsorption for them. As adsorption is manifest by wetting or non-wetting in our case, it is seen that under certain conditions some sulphides can be wetted by water and others not.

In dealing with a solid, water and oil phase the action of adsorption toward the solid will be the algebraic sum of the surface energies of all the material entering into the sphere of action. Hence any substance that tends to upset the surface tension or energy of any one of the three or four phases involved would tend to change the resultant surface energies of all of them and hence upset the conditions that have been established for adsorption of either the water or the gases involved, as the case might be. Therefore, it can be seen that any impurities in solution in the water would tend to affect this algebraic sum and hence upset the necessary equilibrium necessary to float the sulphides

from the pulp. Also, as the surface energy is the product of the surface energy multiplied by the area, the presence of any material having very largely developed surfaces which is of course principally colloidal would tend to upset the equilibrium and hence flotation.

As size is such an important factor, it is plain too that the oil can be too much emulsified. In fact, when the oil is in an extremely colloidal condition it is impossible to get good flotation results. The fact that the same materials which tend to throw the oils out of emulsion are substances that benefit flotation is a proof of this statement.

A practical illustration of some of these things is the case at Inspiration, where it was found to be impossible to float the copper sulphide from the gangue containing large amounts of decomposed material such as koaline, which is of course a colloid. No trouble was encountered, however, in locating the hard undecomposed ore.

There are several different types of colloids, but the most important are the so-called irreversible and reversible colloids. The irreversible colloids are those that are most liable to be present in ore pulps, being iron, aluminium hydroxide, etc. They are called irreversible because it is impossible to put them back in colloidal condition after having once flocculated them by means of an electrolyte.

The reversible colloids are those that can be put back into colloidal condition by simply shaking up after flocculation. They are very inactive toward electrolytes. Among the reversible colloids might be mentioned aqueous solutions of gelatin, glue, gum, tungstic acid and molybdic acid. These materials cause great trouble in flotation and are very difficult to remove.

From this short discussion several conclusions might be drawn. Among them are that colloids interfere greatly with flotation and that in order to overcome the difficulty they must be removed. There are several ways of doing this, among them being preliminary heating of the ore, washing the ore or flocculating it by means of electrolytes. These are, of course, the means of removing irreversible colloids. As far as is known, there is no way at present of overcoming the difficulty due to productive colloids or reversible ones.

### The Graselli Prize

At the meeting of the N. Y. section of the Society of Chemical Industry, on Oct. 25, the honorary secretary, Major Allen Rogers, announced an annual prize in the form of a medal to be given to the author of the paper of the greatest general interest and value presented at any meeting of the New York section of the society during the year. The donor of the medal is the Graselli Chemical Co. and it is to be known as the Graselli prize.

### Ramsay Memorial Fund

More than \$3,000 had been contributed to the Ramsay Memorial Fund in the United States up to Nov. 1. It is hoped that the American subscription may reach \$10,000 by Jan. 1. Checks should be made payable and sent to the Ramsay Memorial Fund Committee, W. J. Matheson, treasurer, 2 Burling Slip, New York City.

## Synopsis of Recent Chemical and Metallurgical Literature

**Magnesium Lead Alloys.**—In a paper read by MR. E. A. ASHCROFT before the Faraday Society at the London meeting in July, 1918, the disintegration phenomenon herein noted, and any prospect there may be of technical utilization of such alloys and their properties, are all based on the accidental discovery made in the course of some other researches of very remarkable properties which are possessed by alloys of metals of the magnesium type with metals of the lead type. The alloys of magnesium with lead—for instance, an alloy of 15 per cent magnesium with 85 per cent lead—will rapidly and completely oxidize in the cold if exposed to atmospheric oxygen and moisture, being then converted rapidly into a “jet-black” powder having the composition of magnesium hydrate and lead sub-oxide or its hydrate. The reaction is complete in a few hours. The water present up to this stage of the reaction does not take any part in the oxidation of the metals, and is not itself decomposed, but combines with the oxide of magnesium and the sub-oxide of lead to produce hydrates, the oxygen absorbed by the metals being obtained from the atmosphere.

For atmospheric oxidation, alloys of 15 per cent Mg are preferable to those of higher content, as the richer alloys (*e.g.*, an alloy of 35 per cent Mg and upward) will not oxidize readily in the cold. By use of this reaction, if sufficient of the alloy be exposed to combine with all the oxygen in any confined space, every trace of oxygen may be removed from any gaseous mixture containing it. It seems therefore possible that such alloys might find useful application both in the laboratory and also in small commercial operations for manufacturing nitrogen from the air and for removing oxygen from any gaseous mixture in the cold. Such a process might, for instance, economically take the place of the last rectifying tower at present used in the large-scale manufacture of nitrogen for conversion to ammonia cyanides or nitrates by liquefaction and fractional distillation of air.

But one may also utilize these magnesium-lead or like alloys for the production of pure hydrogen gas for aircraft or other purposes. For this purpose alloys richer in Mg may be employed, and 35 per cent is a convenient strength. It is only necessary to boil such alloys in water, when reaction takes place as follows:

The reaction (a) takes place briskly. The lesser reaction (b), however, under these conditions proceeds only very slowly, and if it is required to render it rapid and complete, it is preferable to digest the alloy under a steam pressure of 100 lb. to the square inch and a corresponding temperature of about 150 deg. C., when the lead will be completely oxidized to  $\text{PbO}$ , and the theoretical quantity of hydrogen liberated. The hydrogen may be drawn off from the pressure vessel with the steam and collected. From the mixture of hydrates or oxides of magnesium and lead resulting

from the reactions also numerous useful products may be obtained.

The hydrates especially are extremely reactive substances, and are obtained in most suitable condition for subsequent further reactions. For many purposes the mixture of hydrates of lead and magnesium may be used without separation. But separation of the magnesium oxide is also easy if required. As an example of possible utility of the residues, the manufacture may be cited of lead peroxide, which according to the known reaction may be easily produced by passing chlorine gas into water in which is suspended a mixture of  $\text{PbO}_2\text{H}_2$  and  $\text{MgO}_2\text{H}_2$  in molecular proportions. The oxidized alloys may also be employed for the preparation of other lead salts or compounds, and would seem to form a most convenient base for this purpose. For instance, a very fine quality of basic lead carbonate (white lead) may be obtained very easily by acting on the lead hydrate with carbonic acid, either with or without separation of the magnesium. The white magnesium carbonate would probably be no detriment to this product as a pigment, but rather the reverse, as it seems to improve its covering and its drying properties. Litharge and minium may also be obtained from the material very readily, and, if desired, of great purity and excellent physical properties, by simple processes.

The mixture of oxides resulting from the oxidation of these alloys may therefore form a valuable starting-point for other manufactures, and in some instances (such as lead peroxide and white lead) it would seem probable that its use may be economical and may constitute substantial improvements in the known processes of manufacture of these products.

To prepare the alloys of magnesium and lead any convenient method may be employed; for instance, magnesium and lead may be readily fused together under a cover to a temperature of 700 to 800 deg. C., and after mixing thoroughly, cooled out of contact with the air, when complete alloy will be found to have taken place, and the product can be readily broken up. Or magnesium may be precipitated from its salts into the lead by employing alkali metals or alkali metal alloys.

But to render the production of such alloys specially economical it is proposed to electrolyze anhydrous magnesium chloride (which is now being produced commercially and very economically by the process for which British Letters Patent 12,873 and 13,259, both of 1916, were granted) over a cathode of molten lead. In such manufactures the electric energy required is the chief item of cost, and consumption is only 2,000 kilowatt hours per ton of 15 per cent alloy. Thus where electricity is very cheap these alloys can be obtained practically at nearly the same cost per ton as metallic lead, and the resulting useful products and effects may be obtained with a considerable degree of economy.

These alloys furthermore possess the valuable feature that they may be produced where electric energy is cheap, and then transported cheaply in sealed cans and utilized at any remote situation. Thus, for instance, as a source of hydrogen or nitrogen for aircraft or for localized manufactures of ammonia or nitric acid, the cost of transport of the alloy would be only a small fraction of the equivalent cost of transport of the products, or of an equivalent quantity of gases in cylinders. For example, the weight of material transport required to

produce a given quantity of hydrogen at any remote situation will be only as 1 to 6 and of nitrogen as 1 to 10, when compared to the transport of cylinder gases. Also the wear and tear and capital sunk in cylinders and the cost of compression are all obviated. These are very substantial advantages to set against the cost of the alloys, but to them must also be added that in most instances the solid products of decomposition of the alloys are as valuable as (and sometimes much more valuable than) the alloys, so that the gases are obtained as by-products and substantially free of cost.

**Dehydrogenation of Petroleum Oils.**—Dr. A. S. RAMAGE in the *Canadian Chemical Journal* of August, 1918, gives an account of a commercial method of making volatile motor oils from the high boiling point paraffines without decarbonization, part of which we quote:

In my process my endeavor has been not to crack the oil, but to obtain a definite chemical reaction, namely—the dehydrogenation of the paraffine to the olefine. In other words, our product is a motor fuel which practically is 95 per cent olefine—the other 5 per cent being further unsaturated products. Water is always produced in dehydrogenation, and is condensed and separated from the fuel in the receiving tank. The reaction can be carried as far as the aromatic series, depending entirely upon the temperature and length of tube through which the vapors are passed. The reaction is as follows:

The vapors are passed over heated iron oxide  $Fe_2O_3$ . At the temperature for motor fuels of 620 deg. C. the oxygen is taken up with the reduction to the oxide  $FeO$ , at which stage we stop the action, steam out the oils remaining in the oxide for five minutes and re-oxidize with a current of air for fifteen minutes. We are very careful not to allow the reduction to go beyond  $FeO$ , because if metallic iron is formed, cracking immediately takes place with deposition of carbon. The action of dehydrogenation is endothermic, whereas the reoxidization is of course exothermic. The period of dehydrogenation lasts for three hours in practice and the revivification one-half hour.

Our first production was in a laboratory tube, electrically heated, 2 feet long, followed by a tube 3 inches in diameter, 4 feet long—then by a tube 10 feet long 3 inches diameter. Our conversion of the original oil would always run 36 per cent, once run through the tube. Since then we have extended the tube to 24 feet and our conversion averages 90 per cent of the original oil, and the recovery 94 to 95 per cent. No carbon has been produced. After steady running of eight months, the iron oxide was removed from the tube and not a trace of carbon was found in it.

The works were built at River Rouge on a practical scale. After several fires, it was burned down and a new works has been erected at Ecorse.

Furnaces containing tubes 8 inches in diameter and 22 feet long are now adopted as the best length and diameter with the feed of ten gallons per hour per tube. For a motor fuel to correspond with the present ordinance for gasoline, a temperature of 600 to 620 deg. C. is kept in the lower half of the tube. The waste heat from the oil burners heating the lower half of the muffle is led off at the upper end of the furnace, giving a temperature of 400 deg. at the upper end where the oil enters to 600 deg. where the vapors issue. We have found that by this progressive heating of the tube the product is not scorched and comes out of the condensers a deep straw color, whereas the passing of the oil or vapors immediately into 600 deg. C. causes the product to become dark and contain some tar. Progressive heating is one of the features of the process. A simple distillation of the condensate with 1 per cent fuller's earth is sufficient to refine the spirit. If we raise the temperature to 650 deg., we obtain a product running as high as 50 per cent under 120 deg. C. and at 680 deg. C. practically all of our product comes over with an end point between 120 and 130 deg. C. I mention this fact because of its application to not only the aeroplane industry but the production of low boiling olefines as a starting point in the organic chemical field.

It is perfectly feasible and does not add materially to the cost to obtain 80 per cent of the original oil with an end point of 45 deg. C. being composed of amylene and low boiling point olefines. One particular point about olefines is the wonderful solubility of ethylene in them. Ethylene is produced in quantity when we are running to obtain very low boiling point spirits, and the gas is compressed and passed through the spirit under pressure of 100 pounds to the square inch. Fifteen times the volume of ethylene is absorbed, and the peculiar point is that after releasing the pressure the ethylene is not given off at normal temperature but seems to be held in some loose form of combination, because at between 40 and 50 deg. C. it begins to come off in great volume. The fact that this gas is dissolved in the motor fuel in such loose form connection as to be so readily given off probably accounts for the quickness with which this fuel ignites, even below zero.

Of more interest to chemists are the products obtained upon further dehydrogenation. Practical results have shown us that with the tube length of 50 feet, and a feed of ten gallons per hour, from 20 to 30 per cent toluol can be produced, not counting the other aromatics. In toluol production the upper end of the tube is kept at 400 and the lower end at 750 deg. C. In the conversion of xylol,  $C_8H_9(CH_3)_2$ , as high as 72 per cent has been obtained of the benzol-toluol fraction containing 30 per cent benzol; the balance toluol. In the separation of aromatics from olefines present the usual sulphuric-acid treatment is followed. I find, however, that this reaction which has always been used is very incorrect and not more than 20 per cent of olefine is reacted upon, the balance of the olefines being polymerized to high boiling point olefines. It can be seen by the simple dehydrogenation of the petroleum oils we are in a position to produce olefines, acetylenes, terpins and the aromatics, and from these bodies the alcohols and various organic products.

## Recent Chemical and Metallurgical Patents

**Universal Soap Dyes.**—Fast on cotton, linen, wool, silk or mixtures.

Dyes for use in coloring textile fabrics in the household laundry have been long on the market. Recently new developments have been made in the manufacture of these materials, a description of which is found in the patents recently allowed to CHARLES C. HUFFMAN of Chicago, Ill. Browns from copper to chocolate shades; blues from baby to navy; reds through flesh pink, rose, salmon, orange, old rose, lavender and purple; yellows and greens, are all compounded from four prominent commercial coal tar dyes: aniline acid red, methylene blue, chrysoidin yellow and a direct black.

Mr. Hoffman states that his improved dye soap should not be confused with those in which the soap acts merely as a carrier or vehicle for the dye, as peculiar reactions take place between the dyes used and the soap, which give a different product than hitherto obtained. One of the important distinctions of the new dye compound is that it is alkali proof, irrespective of the prior basic, acid or neutral characteristics exhibited by the dye before combining with the soap.

A still further distinction is that these dyes are universal, that is, adaptable directly to either cotton, linen, wool, silk or mixtures thereof. The greatest advantage, however, is that temperature, time and concentration of the dye suds do not influence the depth of shade; therefore no special skill is required in matching pieces treated separately.

In producing forty-five pounds of soap dye, about twenty-five and one-half pounds of olive, soy bean, raisin, peanut, corn or any vegetable oil are saponified in the cold with thirteen and a quarter pounds of sodium hydroxide solution (sp.gr. 1.40 at 65 deg. F.). When the reaction is nearly complete, one gallon of boiling dye solution is added to the incompletely saponified oil soap emulsion. The heat of the reaction together with the heat supplied in the added boiling dye solution serves to raise the temperature of the mixture to approximately 122 deg. F., at which temperature the dye reacts with the free sodium hydroxide, forming a sodium salt of the dye acid with the elimination of a molecule of water. The formula of the resulting dye has not been determined; none of the reactions characteristic of the dye acid remain, however, so that a new compound is thought to exist.

In ordinary solutions, chrysoidin yellow will precipitate aniline acid red and the latter will throw methylene blue out of its solution. In making browns by this process, all three of these dyes exist in solution simultaneously. A medium shade of brown is produced by adding to the emulsion a quart each successively of the following boiling dye solutions:  $7\frac{1}{2}$  oz. chrysoidin yellow,  $7\frac{1}{2}$  oz. aniline acid red, 5 oz. direct black and  $\frac{1}{2}$  oz. methylene blue. Greens are prepared by adding 2 quarts of boiling chrysoidin yellow solution followed by a like amount of methylene blue. The intensity of the various shades depends on the amounts of dye acids compounded into the soap emulsion and the colors on

their relative proportions, so that color matching will not be left to the skill of the user. (July 30, 1918; 1,274,046-017-048-049.)

**Separation of Alunite from Gangue.**—CARL F. HAGEDORN of Chicago notes that the specific gravity of alunite and its associated rhyolitic gangue is so nearly equal as to prevent gravity concentration. He therefore recommends a preliminary calcination of the material, crushed to  $\frac{3}{4}$ -inch, in a rotary kiln operating at about 1000 deg. C. The kiln and temperature should be so adjusted that practically all of the  $\text{SO}_2$  is driven off during the two or three hours the particles are in the kiln. High temperatures are to be avoided, since they volatilize potash. The inventor specifies that the fuel shall be oil, gas or other non-silica bearing material, noting the fact that the fine ash from pulverized coal adheres to the calcine and fluxes the various constituents in such a way that further separation is retarded. After calcination the gangue material is of its original texture but the alunite has been disintegrated so that separation in many known ways is easy. Simple screening is suggested for the separation of the fine alumina and potash from the coarser particles of rhyolite. A particularly advantageous method of separating the potash consists in digesting the calcined materials in an autoclave at about 60 pounds pressure and a temperature high enough so that the contents may not cool below 90 deg. C. until after they have been filtered. Only sufficient water is introduced to take the  $\text{K}_2\text{O}$  in saturated solution at 90 deg. C. After digestion the sludge is separated from its coarser and heavier particles of gangue in a V-box or de-watering cone, the overflow of which contains the finest and purest alumina in suspension and the potash in solution. (1,253,590 and 1,253,591; assigned to Mineral Products Corporation; Jan. 15, 1918.)

**Aluminates from Alunite.**—P. R. HERSHMAN of Chicago, Ill., has already patented (1,191,104) a method of obtaining soluble potassium aluminate from alunite. He has now discovered that practically complete extraction of the potassium may be had by the following process: Mix 30 parts of calcium oxide with 100 parts of pulverized alunite, heat the mass in a muffle to 1000 deg. C. in the presence of steam, when a water soluble compound corresponding to the formula  $\text{K}_2\text{O} \cdot 2\text{Al}_2\text{O}_3$  is formed. This is removed by leaching, and the potash-free residue containing about 60 per cent of the alumina may be further treated as follows: Barium sulphate and calcium oxide are each added to the residue in molecular proportions to the alumina contained, and the mixture heated in a muffle furnace for about three hours in the presence of superheated steam. The greater part of the barium and aluminium forms a soluble barium aluminate which may be extracted with hot water. The compound is of value as a ready source of pure alumina.

Barium aluminates of the formula  $\text{BaO} \cdot \text{Al}_2\text{O}_3$  or  $2\text{BaO} \cdot \text{Al}_2\text{O}_3$  may also be made of the residue from the sodium aluminate leach by mixing with barytes, together with considerably more carbon than is required to effect the reduction of the latter to the sulphide. The mass is pulverized to 100 mesh and is heated for four hours at 1050 deg. C. in a muffle furnace through

which is passed a slow current of reducing gas and steam. The excess carbon, steam and reducing gas maintain an atmosphere containing more or less CO, which is of use in preventing the decomposition of the barium aluminate by CO. During the operation elemental sulphur is driven off, which may be collected by known methods. (1,240,571-2 and 8; assigned to Armour Fertilizer Works; Sept. 18, 1917.)

**Pure Alumina from Alunite.**—HOWARD SPENCE and W. B. LLEWELLYN of Manchester, England, note that the residue from leached calcined alunite contains so many impurities, such as iron and silica, as to render it unfit for use in metal or abrasive manufacture without further purification. They therefore propose to ignite the alunite in such a manner as to produce maximum solubility, to pulverize the calcine and to hydrate the mass in the cold for several weeks in liquor from a previous operation. The hydrated material is then agitated for a few hours in a series of closed vessels during the passage of SO<sub>2</sub>, maintaining a temperature of 40 deg. C. The solution is now tested for SO<sub>4</sub> ion, and any excess over 0.9 mols Al<sub>2</sub>O<sub>3</sub> is removed by the addition of the proper amount of lime. If there remains any excess sulphate the precipitated aluminium will contain basic double alkali aluminium sulphate and considerable alumina will remain in solution. After filtration, the clear liquor is heated out of contact with air, the SO<sub>2</sub> driven off is re-used, and over 90 per cent of the alumina is thrown down as a granular basic sulphate which filters easily. Practically all of the iron remains in the solution if air has been properly excluded. The precipitation is best effected in dilute solution containing about 5 per cent Al<sub>2</sub>O<sub>3</sub> to prevent the formation of double salts. The basic precipitate contains about 30 per cent Al<sub>2</sub>O<sub>3</sub>, and may be converted into the latter by ignition. (1,256,605; Feb. 19, 1918.)

**Potassium Nitrate from Alunite.**—H. J. DETWILLER of Allentown, Pa., proposes to digest powdered alunite with boiling nitric acid, taking into solution all the potassium and aluminium as nitrates and sulphates. Fine silica remaining may be removed by filtration and marketed for the manufacture of water glass or polishes. The aluminium in the filtrate is precipitated by the addition of KOH in quantitative amounts under constant agitation, and the aluminium hydrate removed by filtration. This is ignited into Al<sub>2</sub>O<sub>3</sub> and is ready for use in the manufacture of metal, alums or other chemical products. The clear liquor is agitated and boiled with a quantitative amount of powdered barium carbonate to remove the sulphate radicle. The precipitated barium sulphate is the well-known blanc fixe of commerce, of extended use as a pigment and size. Carbonic acid is now removed by the addition of nitric acid, and the remaining solution, containing only potassium nitrate, crystallized to saltpeter, used in explosive manufacture, fertilizers and chemical industry. (1,274,145; July 30, 1918.)

**Continuous Roaster-Extractor.**—W. M. E. GREENAWALT of Denver, Colo., patents a process of roasting and extraction, where the roasting is done in a vertical shaft of considerable height and with closed top. Across the bottom are a series of pipes perforated with fine holes, through which air and any other gas desired

to participate in the reactions are introduced. The roasted ore is passed between the tuyere pipes into a downward extension of the shaft submerged in a tank of water or other solvent, and is fed into the solution gradually by a mechanical feeder. A drag conveyor removes the leached ore, while the overflow removes fines and slimes in suspension in the solution. The method applies blast roasting so that the heat in the calcine is utilized to facilitate leaching, and losses of dusting are overcome. (1,218,996; Mar. 13, 1917.)

**Introducing Fuel Through Tuyeres.**—THOS. W. CAVERS of Copperhill, Tenn., patents the method of introducing all or part of the fuel needed in matte smelting in blast furnaces through the tuyeres, according to the diagram shown herewith. The bustle pipe 6 delivers air under pressure through the tuyere 4 into the furnace slightly above the slag line 5. Fine coal is discharged simultaneously from hopper 10 by means of

TUYERE AND FEEDING APPLIANCE

screw conveyor 11 and pipe 9. He finds that in working a certain sulphide charge semi-pyritically it has been necessary to add approximately 6 per cent coke to the ore and flux at the top of the furnace column. Except when starting the furnace, coke additions may entirely be supplanted in the new practice by approximately four per cent of fine coal, of inferior bituminous grade. Pulverization is not needed; the pieces of coal should be merely sufficient to allow uniform delivery without danger of clogging the piping. Sulphide ores, plus necessary fluxes, may also be introduced in this manner; fuel oil may be utilized instead of coal if it is more readily obtainable. In this manner the fuel is burned very close to the focus where it is needed, the focus is substantially lowered, and the top of the ore column is much cooler. The introduction of all or part of the fuel in the smelting of oxidized ores to a matte is also feasible; an oxidizing atmosphere must be maintained in the smelting zone, to prevent the formation of metallic "sows." (1,259,467; Mar. 12, 1918.)

## Aluminium and Its Light Alloys—VI

## Bibliography (b)

BY PAUL D. MERICA

THE following continuation of the Bureau bibliography on aluminium and its light alloys is the supplement to the very comprehensive one assembled by the library of the United Engineering Societies and presented to the Bureau by Professor Zay Jeffries.

The numbers are references from the previous articles on the technology of aluminium in our issue of Aug. 1; light aluminium alloys, Aug. 15; miscellaneous alloys, Sept. 15 and Oct. 1, and duralumin, Oct. 15.

## Book Reviews

HANDBOOK OF CHEMISTRY AND PHYSICS. Fifth Edition, duodecimo (11 x 16 cm.), 414 pages; price \$2.00. Compiled and sold by The Chemical Rubber Company, Cleveland, Ohio, U. S. A.

The company employed Dr. W. R. Veazey and Mr. C. D. Hodgman, of the Case School of Applied Science, to select the data in their first edition; Prof. M. F. Coolbaugh of the same institution assisted Mr. Hodgman in the present revision. A large number of the tables have been revised, and numerous new ones added.

There is an immense amount of useful information between the covers of this book, and it is wonderful book-value for the money—as book prices go. But there is also a regrettable amount of misinformation mixed in with the good, a deplorable tendency to prepetuate ancient and honorable mistakes of earlier tables, and an exasperating absence of many well-known data. All the instances justifying this criticism cannot be catalogued, but examples of them are the following: The heats of formation comprise only three pages in large type, giving only part of Thomsen's results, which date from somewhere in the last century; not a single thermochemical value determined in the last twenty-five years is given. Many of Thomsen's values have been improved upon and hundreds of thermochemical data obtained since Thomsen died, but thermochemistry expired with Thomsen, as far as this handbook is concerned; furthermore, not over 10 per cent of the really important data determined by Thomsen are quoted in it. In the tables of physical constants of inorganic compounds, the melting

points of cerium, chromium, silicon and titanium are omitted as though unknown, those of magnesium, manganese, molybdenum, palladium, strontium and tantalum are given wrongly, in some cases several hundred degrees in error; tungsten is said to melt "above 1900 deg.," whereas for at least five years it has been known to melt above 3000 deg. Much of the information in this important table is ten years old or more, and frequently unreliable, in the light of more recent determinations.

The general characteristics of the tables containing miscellaneous information are the absence of the most modern or most accurate data, and their incompleteness. We regret to see students and practical men fed such scientific husks, because it inevitably leads to sloppy pseudo-science, which we had hoped was diminishing. There are better and more accurate chemical and physical handbooks on the market. In such a situation, the reviewer's advice would be to get the best or none; do not waste money on a book containing some unreliable tables, while purporting to give the most reliable data known.

**MINING ENGINEERS' HANDBOOK**, *Robert Peele*, editor-in-chief. First edition; 2375 pages;  $4\frac{1}{2} \times 7\frac{1}{2}$ ; red fabricoid; illustrated. Price \$5.00. New York: John Wiley & Sons.

The scope of this handbook is quite extensive, having besides the sections dealing with mineralogy, ore deposits, methods of prospecting, exploration and mining, and mining equipment, a good selection of civil, electrical and mechanical engineering subjects, economics and law. The staff of editors is very well chosen: mineralogy, A. J. Moses; geology and mineral deposits, J. F. Kemp; earth excavation, H. P. Gillette; explosives, Haskell, Holmes, J. a Motte and Le Maistre; rock excavation, H. P. Gillette; tunneling, Brunton-Davis; shaft-sinking in rock, H. L. Carr; shaft-sinking in alluvial soils, F. Donaldson; boring, A. F. Taggart; prospecting, development and exploitation of mineral deposits, J. F. McClelland; underground transport, E. C. Holden; hoisting plant, shaft pockets and ore bins, W. M. Weigel; drainage of mines, R. A. Norris; mine ventilation, F. E. Brackett; compressed air plant, R. T. Dana; electric power for mine service, G. R. Wood; surveying, Chas. B. Breed; underground surveying, Ed. K. Judd; mine geologic maps and models, R. H. Sales; mine organization and accounts, J. R. Findlay; cost of mining, J. R. Findlay; wages and welfare, E. K. Judd; mine air, hygiene and accidents, G. S. Rice; mining laws, H. V. Westervelt; mine examination, valuations and reports, W. Y. Westervelt; aerial tramways and cableways, E. B. Durham; mechanical conveyers, L. De G. Moss; ore dressing, R. H. Richards; ore sampling, T. R. Woodbridge; assaying, E. J. Hall; testing of ores, J. E. Clennell; notes on selling, purchasing of ore, A. L. Walker; gold amalgamation and cyanidation, E. A. Dufourcq; preparation and storage of anthracite coal, P. Sterling; preparation and coking of bituminous coal, H. M. Conner; mathematics and mechanics, C. H. Burnside; elements of hydraulics, J. K. Finch; engineering thermodynamics, E. D. Thurston; steam engines, boilers, pumps, turbines, gas engines, Parr, Thurston and Herrick; mechanical engineering, miscellany, Thomes and Parr; electrical engineering, W. I. Slichter; elements of structural design, J. K. Finch; general tables. While it has been customary to make engineering handbooks more or less dependent upon one another and to give thorough treatment in their limited field, the policy of this handbook is to furnish the mining engineer with a ready reference book on all subjects most likely to demand reference without regard to the other special handbooks he might be expected to have.

## Personal

MAJOR SAMUEL AVERY, chief of the university relations branch of the Chemical Warfare Service, resigned his commission on Dec. 1 in order to resume his duties as chan-

cellor of the University of Nebraska, Lincoln, Neb. This resignation has been permitted by the War Department at the request of the Board of Regents of the University of Nebraska. MAJOR VICTOR LENHER, in addition to his other duties in the relations section, now takes charge of the work relinquished.

MR. E. A. CAPELEN SMITH has been elected vice-president of the Chile Exploration Co. and the Braden Copper Co.

MR. H. C. CHAPIN has severed his connection with the National Carbon Co., Cleveland, Ohio, to become associate professor of chemistry in Lafayette College, Easton, Pa.

MR. W. DEWEY COOKE, secretary and sales manager of the Southern Fertilizer & Chemical Co., Savannah, Ga., has been commissioned first lieutenant in the gas and flame division of the Chemical Warfare Service.

DR. HERMAN FLECK has been appointed consulting chemical engineer of the Chemical Production Co., operating at Owens Lake, Calif. He will continue to act as consulting engineer to the Chemical Products Co. of Denver, Colo.

MR. ELLWOOD HENDRICK, consulting editor of *Chemical and Metallurgical Engineering*, read a paper before the New York Section of the American Chemical Society at Buffalo on "Chemists in the Future" at the meeting held Nov. 20.

MR. JOHN MCCONNELL, metallurgical and engineering adviser of the United Alloy-Steel Corporation, Canton, Ohio, has resigned. He is now connected with the Interstate Iron and Steel Co., Chicago, Ill., where he has charge of producing alloy steels.

MR. JOHN J. PORTER, first vice-president of the Security Lime & Cement Co., Hagerstown, Md., has been given a Government appointment as a dollar-a-year man. He is to act as potash expert for the Bureau of Mines and to help in working out plans for increased potash production.

MR. H. DEWITT SMITH has been appointed to a position with the Aircraft Production Board and will be stationed at Dayton, Ohio. He was formerly mine superintendent at the United Verde Copper Co., at Jerome, Ariz.

MR. HENRY P. WALTERS, recently in charge of the picric acid works of the Smet-Solvay Co., Split Rock, N. Y., has been selected to take charge of the new picric acid works now being erected for the Government at Grand Rapids, Mich.

## Obituary

MR. HOWARD S. LEE died on Oct. 25 of influenza at Silverton, Col., at the age of 38. Ten years ago he became associated with the United States Mining, Smelting & Refining Co., and since then had managed several properties of that company. Recently he had been promoted to the position of assistant to the chief consulting engineer, with headquarters in San Francisco.

## Current Market Reports

### The Non-Ferrous Metal Market

*Friday, Nov. 22.*—The non-ferrous metal market has not excited any interest, the war prices still prevail except in the cases of tin, zinc and antimony, the former of which is expected to continue to decline.

*Aluminum.*—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

*Antimony.*—The volume of sales is increasing at prices from 84c. to 85c. per pound.

*Copper.*—The price of \$520 per ton for carload lots and 27.3c. per pound for small quantities was continued for another period at the conference held on Oct. 25 at Washington.

|                            |     |        |           |
|----------------------------|-----|--------|-----------|
| Copper sheets, hot rolled  | lb. | \$0 36 | — \$0 37½ |
| Copper sheets, cold rolled | lb. | .37    | — .38     |
| Copper bottoms             | lb. | .44    | — .45½    |
| Copper rods                | lb. | .36    | — .37     |
| Copper wire                | lb. | .29½   | —         |
| High brass wire            | lb. | .28½   | — .29½    |
| High brass sheets          | lb. | .28½   | — .29     |
| High brass rods            | lb. | .26½   | — .28     |
| Low brass wire             | lb. | .32½   | — .34     |
| Low brass sheets           | lb. | .32½   | — .34     |
| Low brass rods             | lb. | .33½   | — .35½    |
| Braided brass tubing       | lb. | .37    | — .39     |
| Braided bronze tubing      | lb. | .42½   | — .44½    |
| Seamless copper tubing     | lb. | .41    | — .43     |
| Seamless bronze tubing     | lb. | .45    | — .46     |
| Seamless brass tubing      | lb. | .37½   | — .39     |
| Bronze (gold) powder       | lb. | 1 00   | 1 75      |

**Lead.**—The lead market is limited by selling restrictions, the supply being allocated by the Lead Committee. In car-load lots at East St. Louis, the price is \$155 per ton. In New York all speculative and traders' lead has disappeared. The Lead Committee apportions lead at 8.55c. to legitimate consumers.

**Manganese.**—The scale prices on page 629 of CHEMICAL & METALLURGICAL ENGINEERING, June 15, prevail; the highest price per unit being \$1.35.

**Silver.**—Due to the flow of silver to Asia in payment for munitions and the greatly increasing industrial consumption in photography, motion picture reels and silverware, there is a shortage of silver even at the present government price of \$1.01½ per ounce.

**Tin.**—The Tin Committee of the American Iron and Steel Institute has not yet announced the official price on tin. No doubt an understanding will have to be had with the producers before a final statement can be made public and as they are all in distant foreign countries, considerable time will elapse in intercommunication, with the added possibilities that prices will not be legally fixed but adjusted by economic conditions as to demand. The market is dull at a price of 71c. per pound.

**Tungsten.**—The market is quiet, scheelite bringing as high as \$25.50 per unit; wolframite, \$23.00 and off grade ores as low as \$17.00.

**Zinc.**—The spelter market is firm. East St. Louis is quoting \$164 to \$166 for November, \$160 to \$164 for December, \$158 to \$162 per ton for January. New York prices are from \$170 to \$174. Zinc dust, 13½c. to 16c. per pound. Sheet zinc, 15c. pound.

#### OTHER METALS

|           |        |               |
|-----------|--------|---------------|
| Bismuth   | lb.    | \$3 50—\$3 65 |
| Cadmium   | lb.    | 1 50—         |
| Cobalt    | lb.    | 2 50—3 50     |
| Magnesium | lb.    | 1 75—2 10     |
| Mercury   | 75 lb. | 125 00—       |
| Mercury   | lb.    | 1 95—         |
| Nickel    | lb.    | 40—43         |
| Tungsten  | lb.    | 34 00—        |
| Iridium   | oz.    | 175 00—       |
| Palladium | oz.    | 135 00—       |
| Platinum  | oz.    | 105 00—       |

### The Iron and Steel Market

The policy of the Government as to control of industry in connection with the transition from war time to peace time conditions has been quite fully outlined, but this does not determine the prospective course of the market. It is impossible to control trade completely, particularly when the control is intended to be exercised only for a limited period.

As to cancellation of contracts, the Government has adopted positively the policy of cancelling as rapidly as possible all orders for material that will not be needed, provided no work is being done upon the contracts, and of proceeding very slowly with the cancellation of contracts which are in course of being filled. On the one hand it is desired to save as much Government money as possible, while on the other hand it is desired to avoid idleness of plants and workmen.

As to limitations on the consumption of steel, placed to augment the supply of steel for war purposes, all restrictions have been practically removed, the earliest order being dated November 11, the day on which the armistice was declared, while other orders have followed in rapid succession.

As to restrictions upon producing operations, these have

likewise been removed in very large part. The preference list is canceled, and all priority orders, whether individual or automatic, except those involving orders placed by the Navy Department, Fleet Corporation and railroad, telephone and telegraph companies. Inasmuch as priority orders merely prescribed the sequence in which orders should be filled when it was impossible to meet requisite delivery dates on all orders, a very moderate relaxation in the pressure for steel would automatically remove the necessity for priorities. The usual contract between producer and buyer is restored and mills will fill orders in accordance with their own appraisal of the needs of their customers.

As to prices, nothing has been done. The maximum limits prescribed to obtain deliveries through December 31 continue in force. As the quarterly price fixings in the trade have carried no reference to the duration of hostilities or the war, no question came up as to the continuance of the limits to December 31.

#### FUTURE OF PRICES

Under open trade conditions, the natural tendency of the iron and steel market upon the ending of the war has been well understood in all quarters. The common view has been that prices after the war would average below the controlled prices, but whether or not that were to be the case a declining market for a few months would naturally occur, because a full measure of demand would not at once develop. A large proportion of the buying of steel in normal times is for investment purposes. Technically speaking, almost every purchase of steel is an investment. Even the jobber invests, expecting to re-sell, but he may convert his investment into cash within 30 days in some instances. The automobile builder invests and sells the finished car in 60 days or a longer period. Other manufacturing consumers, particularly those making seasonable goods, require longer periods. The investor who builds a factory the product of which has no certain sale for a period of years may expect to amortize his investment in three to five years. Another can look farther ahead. A highway bridge may be a safe investment if it cannot be written off in less than 20 years. Each class of buyers, therefore, has his own period in which he concludes the steel market will not decline, if he is to buy at the time instead of waiting for a lower market. There can be no stable market for steel unless there is demand approximately sufficient to engage all productive capacity, and a demand of that size requires that the major portion of it be for investment purposes, hence there can be no stable market until the balance of probability is that the market will not decline for such a period as the future can be gaged.

The object of control, therefore, is double, to prevent a temporary demoralization in the market, and to develop what is the price level at which the control can be renounced and the market allowed to support itself at that level. To prevent demoralization the view was held that the War Industries Board should for a time fix minimum prices, as it has hitherto fixed maximum prices. The first thought was that possibly the Sherman law stood in the way. The second thought has been that irrespective of the Sherman law, the Government in attempting to fix minimum prices would be abandoning one of its cherished traditions, that "the Government has never bluffed." It has never issued an order unless it could punish violation. When maximum prices were set the Government was in position to commandeer plants and put them on Government orders exclusively if the owners refused to sell at fair prices. It has no means to punish a price cutter. At this writing the common thought is, then, that the War Industries Board will continue to set maximum prices and if the trade can hold together it will adhere to those prices as minimum likewise. As long as the prices are maximum also, they must be kept fairly high, or inroads may be made upon the co-operative spirit that has been so pronounced. As they are kept high, however, the readjustment to lower levels is impeded. Accordingly a thought is rising that when the time comes the War Industries Board will not fix prices for the period after December 31, or if it does will fix them at such levels that the market will be free to depart downwards from them.

Immediately upon the signing of the armistice and the removal of various restrictions upon the production and consumption of steel there developed an insistent demand which has given the market an appearance of strength, but in this case appearances are misleading. The demand is insistent where it exists, but it represents but a small fraction of the total buying public, and only those buyers who see their way clear to liquidate the investment in a very short time. The chief demand has, in fact, come from jobbers and automobile builders. Together these buyers do not normally absorb 20 per cent of the steel output. The jobbing demand is not for the purpose of accumulating stocks, but of securing such material as can be turned over quickly, chiefly before January 1, on which date it is desired inventories should be as low as possible. The automobile builders have some stocks of steel and during the next few months will not require much more than their normal weekly or monthly quota of steel.

This flash of demand will soon be over, and while other buyers will begin to appear in greater volume there will be on the other hand the gradual cancellation of war orders and the balance cannot be struck until real investment buying develops. That will probably require several months at least and thus the balance of probability is that there will be a period of lessened mill operations. When the market has once been established to the satisfaction of investors there is likely to be heavy demand for steel for a period of years. Even in the case of the government itself, while the desire is to avoid a slump in the market, the Railroad Administration is definitely committed to a policy of not making further purchases until steel prices are lower.

### The Chemical Market

**HEAVY CHEMICALS:**—Trading in most all the items that come under this heading has developed a very conservative character and most consumers are averse to purchasing beyond their immediate requirements. Medicinal products again developed a firmer tone toward the latter part of the interval. General market quotations at the present, however, are considerably lower than previously indicated. Other products with but a few exceptions have had a downward tendency in price, particularly caustic soda, which has had a varied experience, though during the close a firmer market was in evidence, due to the possible lifting of the export restrictions which bring about buying interest for foreign account. Soda ash has also been neglected to a very noticeable extent and prices therefore have declined from 5c. to 10c. per hundred pounds, though conditions in the East continue to be somewhat more favorable than those in the West and Middle West.

**Caustic Soda:**—There is an unsteady undertone to the market at present, representing considerable diversity of opinion among traders as to the actual position of this product. Some holders who were offering at \$3.85 early in the week have withdrawn their quotations, although up to the close some material was available in scattered lots at this figure. The more conservative operators are closely watching the trend of the market, in view of the possible developments that may take place at any moment. Advances from the West state prices were advanced for the solid material from 4c. per pound to \$4.10 per hundred pounds, while in the East offerings were free at \$3.90 per hundred pounds ex warehouse. The ground product is also liberal in supply, but there is no particular buying interest in evidence and prices remain firm at \$5.10 per hundred pounds.

**Soda Ash:**—Conditions in this market have been somewhat easier for the past week and in most instances a decline in prices has been in evidence. Bag material during the latter period was generally quoted at from \$2.45 to \$2.50, while offerings of barrels were liberal at \$2.85 and \$2.90. Double bags from Western warehouses were quoted at \$2.85. In Chicago single bags were held at \$2.55 and barrels at \$2.85.

**Zinc Oxide:**—Buyers have been showing very little interest in the item and the only trading noted is that which is passing through routine channels. There are no price

changes reported and quotations generally range from 12½c. to 14c. per pound.

**Yellow Prussiate of Soda:**—There has been a continued depreciation in price for this material and quite frequently cheap lots are available, but despite this condition buyers are not attracted. Offerings of the product are made at from 36c. to 38c.

**Bleaching Powder:**—The government has removed all restrictions on the uses of chlorine and prices therefore have been on the decline. Quantities of the material were offered for bids, with sellers intimating that prices considerably below the market would be accepted, but there was no important trading. Prices for spot material range from 3½c. to 4c. and for that rolling 4c. to 4½c. was the asking price.

**Potash Chrome Alum:**—The market is reported to be quiet and the sales that are passing are consummated at the levels of 20c. to 21c., which continue to be the general quotations heard. Stocks are in fairly good supply and fully in proportion to the current call.

**COAL TAR PRODUCTS:**—Offerings of the products that come under this heading in most instances have developed to an easier position, but trading in general has been quiet during the past two weeks and that which is passing is only for immediate needs, with no disposition on the part of buyers to purchase ahead, owing to the uncertain conditions prevailing. The more conservative operators are just holding back, watching the trend of the market. No important price changes are noted in spite of the continued lull in the situation. However, where effected they have had a downward tendency. As soon as the contemplated cut in ammunition output is established, toluol will be available and the movement will open a wide field now practically closed.

**Toluol:**—Up to the present there is no reportable change of any importance in this market. The item is still under government control and there are no additional releases being granted. However, it is generally believed that all requisitions for December shipment will most likely be fulfilled. Some lots occasionally appear in the resale market at prices above those fixed by the government.

**Xylol:**—The restrictions relative to this item have been lifted and factors state they are in a position to consider business in this direction. Prices remain firm at the generally quoted range.

**Formaldehyde:**—The government ruling for this item as to prices is still in force. Stocks, however, are reported to be scarce and operators in the resale market are asking from 3c. to 4c. above these figures. Spot lots are difficult to locate and appear only in scattered lots.

**Para Amidophenol:**—Developments for this material have been such that many factors are out of the market owing to their sold up condition. However, available supplies are sufficient for current requirements, and those who have material to offer are still quoting prices at the same levels for both the base material and the H. C. L.

**Dip Oil:**—Manufacturers are in a position to fulfill all requirements of this product and prices are firm.

**Phenol:**—A rather uneasy undertone is prevailing in this market, as there are many manufacturers of this product who were kept busy on government requirements, and the more conservative operators are inclined to await developments before continuing to manufacture. Prices have declined from 2c. to 3c. per pound.

**Benzol:**—There has been a fairly active inquiry for this material and while its production has been plentiful and at the present writing a surplus of stocks is on hand, factors believe this product will again come to the front through its use for automobile propulsion, but this is only an opinion offered by some who are in close touch with the situation. Prices at the moment are firm for material in tank cars and in drums.

**Orthotolidine:**—Offerings of this product are reported to be somewhat more liberal and a rather strong demand is in evidence, but trading is of a routine nature, with no important interest otherwise noted. Quotations generally heard remain at the same firm levels.

General Chemicals

| WHOLESALE PRICES IN NEW YORK MARKET NOV. 22, 1918    |         |                          |
|------------------------------------------------------|---------|--------------------------|
| Acetic anhydride.....                                | lb.     | 1.60 — 1.85              |
| Acetone.....                                         | lb.     | .25 — .251               |
| Acid, acetic, 28 per cent.....                       | cwt.    | 5.96 — 6.11              |
| Acetic, 56 per cent.....                             | cwt.    | 10.76 — 10.87            |
| Acetic, glacial, 99 1/2 per cent., carboys.....      | cwt.    | 19.00 — 19.20            |
| Boric, crystals.....                                 | lb.     | 1.31 — 1.5               |
| Citric, crystals.....                                | lb.     | 1.02 — 1.05              |
| Hydrochloric, C. P.....                              | lb.     | Nominal                  |
| Hydrofluoric, 30 per cent, in barrels.....           | lb.     | .05 — .081               |
| Lactic, 44 per cent.....                             | lb.     | .15 — .16                |
| Lactic, 22 per cent.....                             | lb.     | .06 — .07                |
| Molybdic, C. P.....                                  | lb.     | 6.90 — 7.40              |
| Nitric, 16 deg.....                                  | lb.     | .081 — .10               |
| Nitric, 42 deg.....                                  | lb.     | .40 — .43                |
| Oxalic, crystals.....                                | lb.     | .40 — .43                |
| Phosphoric, 47-50 per cent paste.....                | lb.     | .071 — .10               |
| Phosphoric, ref. 50 per cent.....                    | lb.     | .35 — .40                |
| Picric.....                                          | lb.     | .75 — .85                |
| Pyrogallol, resublimed.....                          | lb.     | 3.25 — 3.50              |
| Sulphuric, 60 deg.....                               | ton     | 16.00 —                  |
| Sulphuric, 64 deg.....                               | ton     | 25.00 —                  |
| Sulphuric, oleum (Fuming), tank cars.....            | ton     | 60.00 — 65.00            |
| Tannic, U. S. P., bulk.....                          | lb.     | 1.40 — 1.95              |
| Tartaric, crystals.....                              | lb.     | 1.70 — 1.75              |
| Uregetic, per lb. of W.....                          | gal.    | 4.91 —                   |
| Alcohol, sugar cane, 188 proof.....                  | gal.    | .911 — .92               |
| Alcohol, wood, 95 per cent.....                      | gal.    | .69 —                    |
| Alcohol, denatured, 180 proof.....                   | lb.     | .06 — .061               |
| Alum, ammonium.....                                  | lb.     | .18 — .19                |
| Alum, chrome ammonium.....                           | lb.     | .20 — .22                |
| Alum, chrome potassium.....                          | lb.     | .091 — .10               |
| Alum, chrome sodium.....                             | lb.     | .02 — .021               |
| Aluminum sulphate, technical.....                    | lb.     | .031 — .04               |
| Aluminum sulphate, iron free.....                    | lb.     | .01 — .09                |
| Ammonia, aqua, 26 deg, carboys.....                  | lb.     | Nominal                  |
| Ammonia, anhydrous.....                              | lb.     | .12 — .13                |
| Ammonium carbonate.....                              | lb.     | (Fixed Price) .071 — .08 |
| Ammonium nitrate.....                                | lb.     | 5.30 — 5.35              |
| Ammonium sulphate domestic.....                      | gal.    | .091 — .13               |
| Arsenic, white.....                                  | ton     | 80.00 — 90.00            |
| Arsenic, red.....                                    | ton     | 65.00 — 67.00            |
| Barium carbonate, 99 per cent.....                   | ton     | 70.00 — 80.00            |
| Barium chloride.....                                 | ton     | .02 — .14                |
| Barium sulphate (Blanc Fixe, Dry).....               | lb.     | .30 — .32                |
| Barium nitrate.....                                  | lb.     | .031 — .04               |
| Barium peroxide, basis 70 per cent.....              | lb.     | .081 — .08               |
| Bleaching powder, 35 per cent chlorine.....          | lb.     | .75 — .75                |
| Borax, crystals, sacks.....                          | ton     | .04 — .05                |
| Bromate, crystals.....                               | lb.     | .15 — .17                |
| Bromine, technical.....                              | lb.     | 1.50 — 1.70              |
| Calcium, acetate, crude.....                         | lb.     | .22 — .23                |
| Calcium, carbide.....                                | lb.     | .09 — .091               |
| Calcium chloride, 70-75 per cent, fused, lump.....   | ton     | .08 — .09                |
| Calcium peroxide.....                                | lb.     | .45 — .45                |
| Calcium phosphate.....                               | lb.     | 1.10 — 1.50              |
| Calcium sulphate, 98-99 per cent.....                | lb.     | .62 — .72                |
| Carbon bisulphide.....                               | lb.     | 4.00 — 4.05              |
| Carbon tetrachloride, drums.....                     | lb.     | .071 —                   |
| Carbonyl chloride (phosgene).....                    | lb.     | 1.65 — 1.65              |
| Caustic potash, 88-92 per cent.....                  | 100 lb. | .021 — .021              |
| Caustic soda, 76 per cent.....                       | lb.     | .30 — .31                |
| Chlorine, liquid.....                                | lb.     | .75 — .78                |
| Cobalt oxide.....                                    | lb.     | .68 — .73                |
| Copperas.....                                        | lb.     | 3.621 — 3.90             |
| Copper carbonate.....                                | lb.     | .161 — .16               |
| Copper cyanide.....                                  | lb.     | .63 — .65                |
| Copper sulphate, 99 per cent, large crystals.....    | lb.     | 4.25 — 4.30              |
| Cumol of tartar, crystals.....                       | lb.     | .13 — .15                |
| Epsom salt, bags, U.S.P.....                         | 100 lb. | .17 — .171               |
| Formaldehyde, 40 per cent.....                       | lb.     | .15 — .18                |
| Glabner's salt.....                                  | lb.     | Nominal                  |
| Iodine, bulk, C. P.....                              | lb.     | 1.12 — 1.15              |
| Iodine, resublimed.....                              | lb.     | .16 — .17                |
| Iron oxide.....                                      | lb.     | 2.05 — 2.05              |
| Lead acetate, white crystals.....                    | lb.     | .17 — .17                |
| Lead arsenate (Paste).....                           | lb.     | .24 — .24                |
| Lead nitrate.....                                    | lb.     | .22 — .24                |
| Litharge, American.....                              | lb.     | 1.40 — 1.65              |
| Lithium carbonate.....                               | lb.     | 18.00 — 20.00            |
| Magnesium carbonate, technical.....                  | lb.     | .12 — .12                |
| Nickel salt, single.....                             | lb.     | .14 — .15                |
| Nickel salt, double.....                             | lb.     | .12 — .13                |
| Phosgene (see Carbonyl chloride).....                | lb.     | 1.10 — 1.50              |
| Phosphorus, red.....                                 | lb.     | 1.00 — 1.15              |
| Phosphorus, yellow.....                              | lb.     | .45 — .46                |
| Potassium bicarbonate.....                           | lb.     | 1.25 — 1.26              |
| Potassium bromide granular.....                      | lb.     | .45 — .46                |
| Potassium carbonate calcined, 85-90 per cent.....    | lb.     | .38 — .40                |
| Potassium chlorate, crystals.....                    | lb.     | .60 — .70                |
| Potassium cyanide, 98-99 per cent.....               | lb.     | 3.75 — 3.80              |
| Potassium iodide.....                                | ton     | 300.00 — 350.00          |
| Potassium murate, 80-85 p. c. basis of 80 p. c.....  | lb.     | .27 — .31                |
| Potassium nitrate.....                               | lb.     | 1.75 — 1.85              |
| Potassium permanganate, U. S. P.....                 | lb.     | 2.30 — 2.50              |
| Potassium persulfate, red.....                       | lb.     | .95 — 1.05               |
| Potassium persulfate, yellow.....                    | lb.     | Nominal                  |
| Potassium sulphate, 90-95 p. c. basis 90 p. c.....   | ton     | .47 — .48                |
| Rochelle salts.....                                  | lb.     | Nominal                  |
| Salammoniac, gray gran.....                          | lb.     | .22 — .24                |
| Salammoniac, white gran.....                         | lb.     | 1.40 — 1.65              |
| Sal soda.....                                        | 100 lb. | 18.00 — 20.00            |
| Salt cake.....                                       | ton     | .12 — .12                |
| Silver cyanide, based on market price of silver..... | oz.     | .631 — .64               |
| Silver nitrate.....                                  | 100 lb. | 2.35 — 2.60              |
| Soda ash, 58 per cent, light, nat (bags).....        | 100 lb. | .60 — 3.75               |
| Soda ash, 58 per cent, dense, flat.....              | 100 lb. | Nominal                  |
| Sodium acetate.....                                  | lb.     | .04 — .041               |
| Sodium bicarbonate, domestic.....                    | lb.     | .24 — .241               |
| Sodium bicarbonate, English.....                     | lb.     | .014 — .221              |
| Sodium bisulfate.....                                | lb.     | .12 — .14                |
| Sodium bisulfite, powder.....                        | lb.     | .25 — .31                |
| Sodium chloride.....                                 | lb.     | .30 — .35                |
| Sodium chromate.....                                 | lb.     | .17 — .18                |
| Sodium fluoride.....                                 | lb.     | .17 — .18                |
| Sodium fluoborate, commercial.....                   | lb.     | .17 — .18                |

|                                             |         |               |
|---------------------------------------------|---------|---------------|
| Sodium hyposulphite.....                    | lb.     | 2.80 — 3.00   |
| Sodium molybdate, per lb. of Mo.....        | lb.     | 2.50 — 5.00   |
| Sodium nitrate, 95 per cent.....            | 100 lb. | 4.75 — 5.00   |
| Sodium nitrite.....                         | lb.     | .35 — .45     |
| Sodium peroxide.....                        | lb.     | .35 — .45     |
| Sodium phosphate.....                       | lb.     | .04 — .041    |
| Sodium prussiate, yellow.....               | lb.     | .03 — .40     |
| Sodium silicate, liquid (60 deg.).....      | lb.     | .03 — .04     |
| Sodium sulphide, 30 per cent, crystals..... | lb.     | .06 — .061    |
| Sodium sulphide, 60 per cent, fused.....    | 100 lb. | .10 — .101    |
| Sodium sulphate.....                        | lb.     | .03 — .06     |
| Strontium nitrate.....                      | lb.     | .25 — .30     |
| Sulphur chloride, drums.....                | lb.     | .071 — .09    |
| Sulphur dioxide, liquid, in cylinders.....  | lb.     | .15 — .16     |
| Sulphur, flowers, sublimed.....             | 100 lb. | 4.75 — 4.50   |
| Sulphur, roll.....                          | 100 lb. | 3.70 — 3.85   |
| Sulphur, crude.....                         | ton     | 65.00 — 70.00 |
| Tin bichloride, 50 deg.....                 | lb.     | .28 — .29     |
| Tin oxide.....                              | lb.     | Nominal       |
| Zinc carbonate.....                         | lb.     | .18 — .20     |
| Zinc chloride.....                          | lb.     | .15 — .151    |
| Zinc cyanide.....                           | lb.     | Nominal       |
| Zinc dust, 350 mesh.....                    | lb.     | .131 — .14    |
| Zinc oxide, American process XX.....        | lb.     | .12 — .14     |
| Zinc sulphate.....                          | lb.     | .041 — .061   |

Coal Tar Products (Crude)

|                                             |      |                    |
|---------------------------------------------|------|--------------------|
| Benzol, pure, water white.....              | gal. | .22 — .27          |
| Benzol, 90 per cent.....                    | gal. | .25 —              |
| Toluol, in tank cars.....                   | gal. | (Fixed Price) 1.50 |
| Toluol, for non-military use, in drums..... | gal. | (Fixed Price) 1.55 |
| Xylol, pure, water white.....               | gal. | .17 — .18          |
| Solvent naphtha, water white.....           | gal. | .18 — .25          |
| Solvent naphtha, crude, heavy.....          | gal. | .12 — .15          |
| Cresote oil, 25 per cent.....               | gal. | .25 — .25          |
| Dip oil, 20 per cent.....                   | gal. | .30 — .32          |
| Pitch, various grades.....                  | ton  | 8.00 — 20.00       |
| Carbolic acid, crude, 95-97 per cent.....   | lb.  | 1.05 — 1.10        |
| Carbolic acid, crude, 50 per cent.....      | lb.  | .60 — .65          |
| Carbolic acid, crude, 25 per cent.....      | lb.  | .35 — .38          |
| Cresol, U. S. P.....                        | lb.  | .19 — .20          |

Intermediates, Etc.

|                                   |     |               |
|-----------------------------------|-----|---------------|
| Alpha naphthol, crude.....        | lb. | 1.00 — 1.10   |
| Alpha naphthol, refined.....      | lb. | 1.50 — 1.60   |
| Alpha naphthylamine.....          | lb. | .55 — .60     |
| Aniline oil, drums extra.....     | lb. | .28 — .30     |
| Aniline salts.....                | lb. | .45 —         |
| Anthracene, 60 per cent.....      | lb. | Nominal       |
| Benzaldehyde (f.f.c.).....        | lb. | 4.25 — 4.50   |
| Benzidine, base.....              | lb. | 1.75 — 1.85   |
| Benzidine, sulphate.....          | lb. | 1.40 — 1.45   |
| Benzic acid, U. S. P.....         | lb. | 3.00 — 3.10   |
| Benzate of Soda, U. S. P.....     | lb. | 2.90 — 3.00   |
| Beta naphthol chloride.....       | lb. | 4.50 — 2.50   |
| Beta naphthol, sublimed.....      | lb. | 10.00 — 12.00 |
| Beta naphthylamine, sublimed..... | lb. | .75 — .85     |
| Dichlorobenzol.....               | lb. | 2.65 — .20    |
| Diethylaniline.....               | lb. | 4.00 — 4.50   |
| Dinitrobenzol.....                | lb. | .36 — .38     |
| Dinitrochlorobenzol.....          | lb. | .40 — .45     |
| Dinitrodichlorobenzol.....        | lb. | .55 — .60     |
| Dinitrotoluidine.....             | lb. | .65 — .75     |
| Dinitrophenol.....                | lb. | .45 — .50     |
| Dimethylaniline.....              | lb. | .75 — .75     |
| Diphenylamine.....                | lb. | 1.00 — 1.10   |
| H-acid.....                       | lb. | 3.25 — 3.50   |
| Metaphenylenediamine.....         | lb. | 1.85 — 2.05   |
| Monochlorobenzol.....             | lb. | .15 — .201    |
| Naphthalene, flake.....           | lb. | .09 — .09     |
| Naphthalene, balls.....           | lb. | .11 — .121    |
| Naphthionic acid, crude.....      | lb. | 1.00 — 1.30   |
| Naphthylamine-sulphonic acid..... | lb. | 1.00 — 1.10   |
| Nitro naphthalene.....            | lb. | .45 — .50     |
| Nitro toluol.....                 | lb. | .55 — .60     |
| Ortho-amidophenol.....            | lb. | 6.50 — 7.00   |
| Ortho-dichlor-benzol.....         | lb. | .15 — .20     |
| Ortho-toluidine.....              | lb. | 1.00 — 1.10   |
| Ortho-nitro-toluidine.....        | lb. | .75 — .85     |
| Para-amidophenol, base.....       | lb. | 4.50 — 5.00   |
| Para-amidophenol, H. C. L.....    | lb. | 4.25 — 5.00   |
| Para-dichlor-benzol.....          | lb. | .15 — .20     |
| Paranitraniline.....              | lb. | .75 — 1.85    |
| Para-nitro-toluidine.....         | lb. | 1.00 — 1.60   |
| Paraphenylenediamine.....         | lb. | 4.00 — 4.50   |
| Para-toluidine.....               | lb. | 2.25 — 2.50   |
| Phthalic acid anhydride.....      | lb. | 4.25 — 5.00   |
| Phenol, U. S. P.....              | lb. | .44 — .44     |
| Resorcin, technical.....          | lb. | 4.50 — 5.00   |
| Resorcin, pure.....               | lb. | 7.00 — 8.00   |
| Salicylic acid.....               | lb. | 1.50 — 2.00   |
| Sulphanilic acid, crude.....      | lb. | .31 — .33     |
| Toluidine.....                    | lb. | 2.50 — 3.00   |
| Toluidine-mixture.....            | lb. | .85 — .90     |

Petroleum Oils

Crude (at the Wells)

|                            |      |             |

## Financial, Construction and Manufacturers' News

### Construction and Operation

#### Arizona

**CONGRESS JUNCTION**—The Octaves Mines Co. will build a 200-ton cold reduction plant.

**GLOBE**—J. F. Mayer, City Clerk, will receive bids until Dec. 5, for building sanitary sewers and sewage disposal plant. Work includes two imhoff tanks, two sludge beds, one chlorinator house, etc. Benham Engineering Co., Colcord Bldg., Oklahoma, City, engineer.

**OATMAN**—The Arizona Mossback Mines Co. will build a 250-ton crushing and cyaniding mill. Estimated cost, \$250,000.

#### Arkansas

**ANDERSON**—The Everton Mining & Development Co. will build a 300-ton washing plant.

**BATESVILLE**—The Reeves Mines will install machinery for a 300-ton washing plant.

#### California

**ATASCADERO**—E. C. Lewis will build a large dehydrating plant here, also several smaller plants at various points in San Luis Obispo County.

**LOS ANGELES**—The New Ellen Potash & Chemical Co., Van Nuys Bldg., will build a castor oil mill, including three-story concrete building. F. L. Stitt, architect, Van Nuys Bldg., preparing plans.

#### Colorado

**BRIGHTON**—The Loveland Natural Food Co. will build a dehydration plant here.

**GREELEY**—The Loveland Natural Food Co. will build a dehydration plant here.

**LONGMONT**—The Loveland Natural Food Co. will build a dehydration plant here.

**LOVELAND**—The Loveland Natural Food Co. will build a dehydration plant here.

#### Connecticut

**HARTFORD**—The Hartford City Gas Light Co., 561 Main St., has awarded the contract for the construction of extensive alterations to its building, to J. H. Grozier Co., 17 Van Dyke Ave. Project includes the erection of a laboratory, offices, etc.

#### District of Columbia

**WASHINGTON**—The Department of Commerce will receive bids until Dec. 4 for the construction of a fishery products laboratory at 6th and B Sts. Address Commissioner of Fisheries.

**WASHINGTON**—The Bureau of Yards & Docks, Navy Department, will build a laboratory building at the Naval Hospital. Estimated cost, \$14,000. Noted Nov. 30.

#### Florida

**FORT MYERS**—The American Fish Products Co. has awarded the contract for the construction of a two-story, 50 x 100 ft. and eight 50 ft. buildings, and will install dehydrating, canning, processing and fertilizer machines. G. S. Stone, manager.

**TAMPA**—The Florida Glass Co. will build a new plant. Estimated cost, \$150,000. E. J. Early, Orlando, president.

#### Illinois

**CHICAGO**—The American Steel & Machine Co., Mansfield, will build a two-story 36 x 72 ft. laboratory. Estimated cost, \$60,000. O. H. Raeder, 20 West Jackson Blvd., architect.

**CHICAGO**—The Barrett Co., 2300 Sacramento St., will improve its plant for the manufacture of coal tar products. Estimated cost, \$20,000.

**CHICAGO**—The Chicago, Smelting & Refining Co., 1325 West 51st St., will remodel the plant purchased from the Hills, Benedict Linsend Oil Co., Loomis St., and will remodel same for its own use.

**CHICAGO**—The Wisconsin Steel Co., 106th St. and Torrance Ave., will build a two-story factory for the manufacture of by-products of coke. Estimated cost, \$65,000.

#### Kentucky

**LOUISVILLE**—The Clay Chemical Co., 1402 Lincoln Bank Bldg., will install a charcoal plant, to include plant for evaporating salt. R. E. Gordon, president.

#### Maryland

**HAGERSTOWN**—The Pangborn Corp. will build a two-story, 40 x 70 ft. laboratory and sand house. Estimated cost, \$5000. W. L. Midekauff, 565 Washington St., superintendent.

**HAGERSTOWN**—The Water Board will enlarge its filtration beds at Bridgeport pumping plant to secure improved facilities for treating water from Antietam Creek. J. McPherson Scott, president.

**INDIAN HEAD**—The Bureau of Yards and Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of a nitrate plant, to the DeKemp Construction Co., 161 Nesbit St., Union Hill, N. J. Estimated cost, \$180,000.

#### Michigan

**GRAND RAPIDS**—The Construction Division of the War Department, Washington, D. C., has awarded the contract for the construction of a picric acid plant to the Owens & Ames Kimball Co. Estimated cost, \$1,000,000.

**GRAND RAPIDS**—The War Department, Washington, D. C., has appropriated \$1,500,000 for the construction of a sulphuric acid plant to be located here.

**HAMTRAMCK**—The Michigan Smelting & Refining Co. will build a two-story, 110 x 140 ft. addition to its plant. Estimated cost, \$100,000.

**PORT HURON**—The Port Huron Sulphite Pulp & Paper Co. will build an addition to its plant.

#### Minnesota

**CALUMET**—The Inter-State Iron Co. will build a two-unit iron ore washing plant having a daily capacity of 1000 tons.

**DULUTH**—The Minnesota Steel Co., Gary St., will build a steel plant. Estimated cost, \$150,000. G. L. Price, vice-president.

**IRONTON**—The Millie Laas Mine has awarded the contract for building a new shop and laboratory to A. G. Gionet.

#### Missouri

**ST. LOUIS**—The St. Louis Surfactant & Paint Co., Arlington St. and Terminal Belt Line, will build an addition to its plant.

#### Montana

**PHILIPSBURG**—The Beaver Mining Co. will build a new manganese mill. Estimated cost, \$25,000.

#### New Jersey

**CRANFORD**—C. E. Kaltenbach, 55 Eglew St., Newark, will build a chemical laboratory here.

**NEWARK**—The Rubber & Celluloid Products Co., 56 Ferry St., has awarded the contract for reconstructing its two-story, 40 x 400 ft. factory, which was recently destroyed by fire, to the American Concrete Steel Co., 31 Clinton St.

**ORANGE**—The Radium Luminous Material Corp., Aiden St., will build a one-story research laboratory addition. R. R. Rowland, superintendent.

#### New York

**BUFFALO**—The Buffalo Paper Furnace Co., Hamburg St., will build an addition to its plant.

**BUFFALO**—G. Elias & Bros., Inc., 965 Elk St., will build a gas product plant.

**BUFFALO**—The National Aniline & Chemical Co., Edgewood Arsenal, will build an addition to its plant here. W. T. Miller, secretary.

**LOCKPORT**—The Isoo Chemical Co. will build an addition to its plant. Estimated cost, \$5000. Evan C. Spelden, vice-president, in charge.

**NEWBURGH**—The G. Washington Coffee Refining Co., 147 41st St., Brooklyn, has awarded the contract for the construction of a coffee refining plant on Mill and William Sts., to the Austin Co., 217 Broadway, New York City.

**NEW YORK**—The Metal Delineating Co., 3 South William St., will rebuild its factory, recently destroyed by fire. Plans call for four two-story, 200 x 400 ft. buildings.

**NEW YORK**—Milliken Brothers, Woolworth Building, has purchased the plant of the James H. Young Stone Co., 136th St. and East River, also the adjoining property, and will build a one-story, 50 x 100 ft. galvanizing plant. Estimated cost, \$25,000. J. E. Jennings, vice-president.

**NIAGARA FALLS**—The Electro Metallurgical Co., Union St., will build an addition to its plant for the manufacture of ferro-alloys. Estimated cost, \$14,000.

**NIAGARA FALLS**—The Republic Carbon Co., Sugar St. and New York Central R. R., has awarded the contract for the construction of a plant consisting of four buildings, to the Lackawanna Bridge Co., Bell and Abby Sts.

**POUGHKEEPSIE**—The Palatine Aniline & Chemical Co., North Water St., will build an addition to its plant. Estimated cost, \$40,000. C. O. Tertwilliger, president.

#### Ohio

**RAVENNA**—The Oak Rubber Co., South Prospect St., will build a three-story addition to its plant on Chestnut St.

#### Oklahoma

**CARDIN**—The Burnham Mining Co. will build a 250-ton mill. E. Van Drevett, superintendent.

#### Pennsylvania

**BELLEFONTE**—The American Lime & Stone Co. will build a new dehydrating plant. Estimated cost, \$400,000. A. C. Morris, president.

**BETHLEHEM**—The Air Reduction Co., 177 Pacific Ave., Jersey City, N. J., has awarded the contract for the construction of a plant here, to James Mitchell, Inc., 76 Montgomery St., Jersey City, N. J. Estimated cost, \$50,000.

**CLARENDON**—The Tiona Refining Co. will build an addition to its oil plant. Estimated cost, \$500,000. R. W. Lavery, 120 Penn. Ave., East Warren, superintendent.

**OAKMONT**—The Edgewater Steel Co., Edgewater Station and Allegheny Valley R. R., has awarded the contract for the construction of a one-story, 160 x 125 ft. factory, to the Austin Co., 16112 Euclid Ave., Cleveland, Ohio. Estimated cost, \$60,000.

**WEST BRIDGEWATER**—The Chippewa Oil Co., Beaver, will build a refinery on Market St. to include pipe line, etc. Total estimated cost, \$60,000.

#### Rhode Island

**PROVIDENCE**—The Providence Dyeing, Bleaching & Calendering Co., 52 Valley St., has awarded the contract for the construction of a two-story, 27 x 50 ft. bleachery in addition to its existing building, to H. E. Mathewson, 97 Peace St. Estimated cost, \$7500.

#### Tennessee

**KINGPORT**—The city has awarded the contract for the installation of a filtration plant to the Pittsburgh Filter Manufacturing Co., Fort Pitt, Pittsburgh, Penn. Estimated cost, \$50,000.

#### Texas

**HOUSTON**—The city will build a sewage disposal plant. Estimated cost, \$75,000. E. E. Sands, city engineer.

**PORT NECHES**—The Magnolia Petroleum Co., Galveston, will build an oil refinery on a site recently purchased here.

#### Utah

**CASTLEGATE**—The Utah Fuel Co. will build a water purification plant to include rapid sand filter, storage tanks, pumping plant and pipe line. Estimated cost, \$10,000.

### Stability of First

#### Importance for Industry

IN a recent address before the American Dyestuffs Manufacturers' Association, DR. F. W. TAUSSIG, Chairman of the United States Tariff Commission, laid down the important proposition: "Stability is of the first importance for any industry and at all times. Business can accommodate itself to almost any conditions, provided they be steadily maintained. This is true as regards prices and wages, banking and monetary systems, income taxes and taxes on business, and, not least, as regards tariff duties. It is quite as important, probably more important, that duties should be settled as that they should be high or low, well or ill adjusted. It is imperative to know on what basis business calculations may be made.

"Not only is this the case with regard to an individual business or a particular industry; it is true also as regards the prosperity of the country at large. Vacillation and uncertainty in tariff policy are probably more harmful than any extreme of high duties or of low duties. The good results which are obtainable through a protective system endure only if such a system is maintained consistently for a considerable period,—if time is given for the development of domestic industries, for growth under assured conditions, for the introduction of improved methods through long-continued experiment. And similarly, the good results which are obtainable under a policy of free trade are dependent upon its maintenance over a long period. They can come only through steady competition among foreign producers and domestic distributors, and the adjustment of export trade as well as of import trade to larger volume. A consistent policy followed for a considerable stretch of time is in either case essential for the attainment of the desired results.

"Let us now look at the situation which is to be expected in the immediate future in this country, and look at it frankly and openly. Let us not disguise the facts by vague generalities, by pleasant words, by rose-colored optimism. The truth, plainly stated, is that the outlook for stability is poor. Indeed, the prospects are of the slightest for anything in the nature of a settlement of the tariff. Consider the obvious facts of the political situation. We are at the beginning of the short session which closes the 65th Congress. In the 66th Congress, which will be in session from March 4, 1919, to March 4, 1921, there will be no unification of control and hence there can be no unification of policy. One party will have a majority in the House of Representatives; the Administration itself is of another party; the Senate will be very evenly divided. Not only this, but the traditional division of opinion and policy on the tariff

will not only be maintained, but is likely to be accentuated. The controversy on the protective policy will go on, and will be conducted on party lines. That controversy, it need hardly be said, is not between protection and free trade. The practical issue is one of degree,—whether there shall be high and strong protection all around, or limited and moderated protection. But the cleavage is clear. I will not undertake to say whether a permanent settlement will ever be reached in this country; but it would seem certain that not even such a provisional settlement as comes by the enactment of a general tariff law is within the bounds of probability for the next two or three years."

Clearly it is of primary importance for all American business men to meet the coming situation. The recent conference at Atlantic City, of which there is an account in this issue, and the Chicago meeting next month of the American Institute of Chemical Engineers are to serve as national clearing houses of thought. Stability in business depends on the business men getting together and taking united action.

## That Missing Page

### From the Blue-back Speller

**A**N OLD "blue-back speller" still lingers in the minds of many of us as the staunch craft in which we were launched into this motley world of art and science. In the well-thumbed volume which was ours in those carefree days there was—how vividly we recall it!—a page torn out by some prior owner, probably as the instrument for some boyish class-room prank. Alas, years have passed, and with them the soiled blue-back with its missing page. Yet sometimes when sitting down to write a bit, and that trenchant word which polishes some epigrammatic phrase is laboriously evolved, we are compelled to pause for the spelling of it—should there be an "i" or an "a"? And then flashes suddenly into memory the missing page in the "blue-back," and it is beyond peradventure that this much-needed word once had there its proper place.

During the war hundreds of chemists and metallurgists were engaged in the most varied researches. But far too often they were confronted with a lack of knowledge concerning some very simple phenomenon, which, according to all the laws of common sense, should have been set down in black and white in that other primer which the earnest seekers after truth have written large in technical literature. It is on the missing page!

To be specific: The efficient use of manganese ferro-alloys is a matter of national interest, not only from the standpoint of economy in ferro-manganese but of more dependable metal—say gun-linings to be used overseas. Colonel W. P. BARBA of the Ordnance Department, in discussing the recent paper of Professor HOWE on "The Erosion of Guns," seriously questioned the practice of adding cold lumps of ferro-manganese to steel in the ladle, and pointed out that segregation was to be expected due to failure of the lumps to melt with sufficient rapidity to diffuse through the bath. If a change in steel-works' practice would help to safeguard the lives of our gunners "over there," we should have moved heaven and earth to put it into effect.

Before being able, however, to come to a decision as to the validity of the point raised, certain information of a very simple nature is needed. How long does it

take a piece of cold ferro-manganese the size of a walnut to melt when in contact with molten steel? If it is a matter of only thirty seconds then it would seem that preliminary melting of the ferro-alloy would be unnecessary, in fact undesirable on account of the power cost and the loss of at least some of the manganese. The question of chilling the bath does not seem to enter into the problem, as it obviously does in the case of spiegeleisen additions. If the melting, on the other hand, requires twenty minutes, it is another matter. Once the lump is melted, it would not seem to matter exactly at what part of the ladle it began to diffuse into the steel bath, since, in these circumstances, diffusion is a very rapid process, especially when aided by the strong convection currents existing in the ladle.

Inquiry among metallurgists of our acquaintance did not uncover any substantiated information as to the approximate length of time it takes such a lump of ferro-manganese to melt. Certainly it is a simple matter to determine experimentally. An electric furnace, a plum-bago crucible or two and a couple of hours, and we venture to say that this very important question could be solved. After this is done, it will be possible to discuss the disadvantages of adding cold ferro-manganese in the ladle more intelligently.

This is only an isolated case where technical progress is hampered by a lack of knowledge regarding fundamentals. Before writing any more essays in these fields we need to get out a revised, complete edition of the scientific "blue-back speller."

## The Smith-Howard Bill

### and Industry's Opportunity

**T**HE Smith-Howard Bill (S-3805 and HR-9686) provides that in each state or territory of the nation there be organized an engineering experiment station in an established university, college or engineering school within its boundaries. The purpose of these stations is to conduct research "in all branches of engineering, manufacturing and the industries, including chemistry, physics, electricity and other sciences." They are also to co-operate with agricultural experiment stations. They are to publish bulletins annually (at least), and these are to give the "results of said researches, investigations and experiments or reports of progress" in relation to the work in hand. The United States Government is to appropriate for each station \$15,000 the first year, \$20,000 the second, \$25,000 the third, \$30,000 the fourth and regularly \$30,000 each year thereafter. The legislature of each state shall designate the institution to engage in such study, subject to the approval of the Secretary of Commerce, who shall indicate lines of inquiry that seem important from a military or industrial standpoint. There is appropriated annually \$25,000 to establish and maintain in the Bureau of Standards a Department of College Research which shall keep all records and extend the facilities of the Bureau as far as is practicable. Provision is also made that the sum of money appropriated for research at any station shall not exceed that actually required for efficient and productive work.

The bill is supported by a committee of which President Maclaurin of the Massachusetts Institute of Technology is chairman, and we have received from Dr. W. Whitney of Schenectady an appeal in its favor.

Of course, under defective administration, the working of the proposed law could be resolved into a mere waste of money, but the time has arrived for us to exercise the quality of faith in our government. The party system under which it operates provides that active and even intense criticism be always maintained, and under this the chances are that a Cabinet member who used these funds for political purposes would soon find himself in hot water. The post of research professor in such institutions is not an easy job for a deserving Democrat or a regular Republican, unless he has the equipment both mental and temperamental to prosecute the work. We are not afraid of politics in this measure, and even if it should creep in, we have abundant faith in the instruments of publicity at hand to put an end to it.

Here is an opportunity for the industries of the country to become interested in and to benefit by the progress of science as it relates to each particular field. It will not take the place of individual or industrial research laboratories. We shall always have progressive men in industry who will keep ahead of the game. And the measure provides two greatly needed features: the opportunity to engage the activities of men gifted with the talent for research to their maximum usefulness for the general welfare, and it will drive into the minds of those industrial administrators who still sorely need it the enlightenment that the ways of stuff are not mystic or esoteric or past finding out, and that the mastery of particles unseen is not a hereditary gift, passed on along with secret formulæ or as the endowment of conjuring. Furthermore the co-operation of the Government in such research work with our educational institutions will undoubtedly be of much fundamental value to the curriculum, the student and industry.

### Steel Consumption and Investments

WITH the removal of Government control from iron and steel prices there is in prospect the form, if not the substance, of an open market. It is improbable that prices will decline at once, for the average producer has no incentive to cut. He has contract business on books, and the contract business can be worked out better if the market does not decline, while there is some demand at current prices and there is practically no latent demand that is awaiting a decline in the market to a certain determined level before it will take hold. How long prices will remain at their present level, or substantially that level, cannot of course be determined.

Perhaps there will be a time when iron and steel producers will be criticised for not reducing their prices, on the ground that development work is held back by iron and steel not being available at prices that would encourage buying. Circumstances are such as to develop a distorted view of the economics of the case. The cost of steel is a definite thing, while the cost of consuming steel is an indefinite thing. The one is quoted in market reports, the other is not. One can refer to current reports and see that structural shapes are priced at three cents a pound, and historical records can readily be consulted to show, for instance, that in occasional instances in the past they sold at a cent a

pound or a trifle more, also that the average quoted market price in the ten years before the war was just a trifle over a cent and a half a pound. Thus we have a cent a pound, a cent and a half a pound and three cents a pound, which is all very precise and concise, and also accurate, which is another matter, for accuracy is not a necessary attendant of precision and conciseness.

A large part of the steel made is placed in employment rather than consumed or used up. In other words it is an investment. To put steel into use as an investment always costs some money, and usually it costs a great deal. Now, the cost of steel is a matter of market reports and statistics, all clear and plain, but the cost of putting steel into employment is an altogether indefinite thing. It depends on the costs of various commodities and upon the cost of labor, not merely the hourly or daily rate of wages, but the cost of recruiting labor, the cost of supervising it and the hourly or daily work that is done by the labor in return for the amount paid. There are no market reports on this and no statistics easily consulted and covering all cases, like the market price of standard sizes of structural shapes.

By reason of this condition, the average observer, if he is not careful and conscientious in his habits of thought, is likely to be impressed by the cost of steel and to lose sight very largely of the cost of utilizing steel. To the investor it is all the same thing. The final cost of his investment, compared with what the cost would be six months, two years, five years, later, is all that he considers. The cost of the steel represents one group of items, the cost of all else another and very large group of items.

The average investment usually represents construction work, in which labor is employed. All wage rates have greatly advanced, but in the steel industry the advance in labor cost is a more definite and clear-cut thing than it is in the case of most construction work. The men at blast furnaces and in steel mills have definite duties to perform, and there has been no great variation in their performance. In the main, they simply receive more money per day. With construction work the variation is much greater, for there are two factors, the hourly or daily rate of wages and the amount of performance. The first had advanced, the second declined. There is room for a decrease in construction costs apart from a decrease in the nominal rates of wages paid. As to construction materials apart from steel, some have advanced more than steel, some less. Some present difficulties in securing deliveries apart from the price, and the progress of construction work requires unanimous consent of all the elements entering. All told, the cost of putting steel into employment is an item that has diverged widely from the former normal, and has shown puzzling trends. It is a more difficult item for the prospective investor to appraise, in relation to conditions that might obtain later, in case he delayed making his investment, than is the item of cost of steel. It may easily require much more time to produce a stable outlook for the cost of employing steel than to produce a stable outlook for the steel market itself. The steel industry, therefore, cannot force the situation by attempting to bargain with the investor. He has other and very important matters he must consider besides the cost of his steel.

## Western Chemical and Metallurgical Field

### The Golden Cycle Cyanide Plant

THE GOLDEN Cycle Mill at Colorado City is the sole survivor of the many plants erected outside the Cripple Creek district to treat the gold tellurides from that remarkable camp. Erected originally as a bromination plant in 1902 by the Telluride Reduction Co., it was converted to the cyanide process four years later, and since that time has been successfully combating, by good management and intelligent metallurgy, the decreasing ore tenure and increasing operating costs. Briefly, the present process consists of crushing, roasting, grinding and classification. The sands are leached and the slime agitated and filtered. About twice as much material goes to the sand tanks as to the slime plant.

Mr. A. L. BLOMFIELD, manager, and Mr. M. J. TROTT, assistant superintendent, recently contributed an important paper to the transactions of the American Institute of Mining Engineers, describing their present roasting practice and pointing out how variations in this department have affected the entire subsequent treatment of the ore. It is a matter worthy of note that while few American gold ores require roasting before cyanidation, the Golden Cycle is the largest mill in the world roasting gold ores, treating 361,000 tons of ore in 1917, valued at 7½ million dollars. Edwards roasters are used, which were developed and universally used in West Australia.

High-grade Cripple Creek ores are treated exclusively. As is well known, these are sulpho-tellurides containing practically no lead, copper, zinc, arsenic or antimony. Of recent years the lime content has tended to increase, so that those ores containing more than 2 per cent CaO are bedded separately from those containing less, the latter comprising about two-thirds of the total. It is essential that the crushing produce a minimum of fines, to prevent excessive dusting in the roasters; on the other hand, coarse particles yield their gold well, it being largely carried in veinlets, but they would contain much unroasted sulphides which deoxidize the solutions and consume cyanide. It has been found practicable to produce a dead-roasted calcine, but careful tests demonstrated that for the conditions existing at the Golden Cycle a soluble sulphur content of 0.10 per cent and soluble sulphide content of 0.10 per cent in low-lime ores (0.15 per cent in high-lime ores) will actually produce a lower residue. Chemical consumption and the dissolution time is somewhat higher, but the roasting is

evidently cheaper. Close control of the heats in the Edwards furnaces is maintained by indicating pyrometers, and chemical control is had by quick methods of analysis, especially developed to supplant the wholly unsatisfactory eye-control. At the same time it has been found possible to halve the dusting in the roasters by baffling the exit gases away from the feed drop-holes, revising the location of the side-doors, submerging the discharge and substituting an open for a revolving cooler. The temperatures in the furnaces at present are about the same as when roasting to 0.05 per cent insoluble sulphur; the feed has merely been increased.

The calcine is ground in Chilean mills with cyanide solution. Quantities of calcium sulphate formed in roasting by reaction between CaO and metallic sulphides go into solution here, to be later deposited in pipes, launders, tanks and filters on cooling, and to "set" the sands in leaching tanks. Roasting practice, therefore, maintains the third firebox at a red heat in order to dehydrate the sulphate and render it insoluble. Wherever practicable, pipes are being re-

FIG. 1. SKETCH OF FLOW OF PULP AND SOLUTIONS GOLDEN CYCLE MILLS

placed by launders in order to remove the incrustation which forms even at best.

An important feature of the process as employed at both the Golden Cycle and the old Portland Mill is the use of blankets for the recovery of the free gold liberated by roasting, and it is of interest to note that one of the oldest known processes for the recovery of gold plays an important function in the modern cyanide

plant. Extensive investigation has shown that this gold in a partially roasted ore is not readily amenable to either cyanide treatment or direct amalgamation. Blanketing was first introduced by Mr. J. M. Tippet at the Portland Mill in connection with the treatment of chlorination tailing. Each Chilean mill at the Golden Cycle is followed by two blanket concentrating tables, being merely apron-plates covered with a cotton bed-blanket. The cleanup is ground in astra and grinding pan, the tails from the final small astra being blanketed before passing into the main mill-feed, and the final concentrate is amalgamated in a barrel in strong cyanide solution.

Such delicately controlled roasting practice is liable to produce calcine of varying quality, especially just after one of the 5000-ton ore beds has been drained and before the new material is properly adjusted. If some insufficiently-roasted material should get into the system, solution of gold would be retarded by the deoxidizing power of the soluble sulphides, and rich residues would result. Rapid leaching of the sands is a precautionary measure attained by freeing them entirely from colloids and by loading the tanks in a semi-dry condition by conveyor and distributor. Desliming is done in a Dorr Bowl Classifier, consisting essentially of a shallow thickener, 13 ft. in diameter, set immediately above the lower compartment of a duplex drag-classifier. The slime overflowing the bowls will run 90 per cent through 200 mesh, the slime plant requiring a minimum of 88 per cent. Sulphides remaining in the slime are neutralized by immediate aeration in a 30 x 10-ft. mechanical-air continuous agitator, as is shown in the diagram, Fig. 1. In addition to these precautions, it is essential that a quick change of solution be made. On the sands this is done by the wash solution in the classifiers. A shallow, primary tray thickener receives the slime overflow from the bowl-classifier, and is of minimum volume so it may be cleared within half an hour.

### Powered Coal for Igniting D. and L. Roasters

**A**N EXPERIMENTAL apparatus has been devised and used at the Midvale Smelter of the United States Smelting, Refining & Mining Co. for determining whether powdered coal could be substituted successfully for the more valuable fuel oil in igniting various lead-cro mixtures on a Dwight and Lloyd roaster. The results have been so gratifying that a permanent installation is now being installed in their roaster plant to serve all of the six machines now running. The permanent installation will contain a Raymond coal pulverizer, the product of which will be delivered by 4-in. screw conveyors to small steel hoppers at each furnace. The coal will then be burned by an apparatus very similar to that found so successful in the experimental work. It is expected that the results will be fully equal to the present; in fact, with some ore-mixtures coal gives a better cake than oil, since the oil flame apparently fuses the topmost surface, restricting the air-flow necessary for roasting and agglomerating the deeper layers. From 450 to 500 pounds of pulverized coal per day will suffice to operate one roaster, in place of 70 gallons of fuel oil.

As shown in Fig. 1, a small variable-speed motor

is belted to a reduction-gear driving at 30 to 40 rotations per minute a 2-in. worm passing through the bottom of the hopper containing pulverized coal. The coal delivered by the worm drops through a 1-in. pipe into a tee, where it meets a stream of compressed air at from 12 to 20 pounds and is then blown into the burner and ignites. The air receiver hides this part

FIG. 1. EXPERIMENTAL POWDERED COAL INSTALLATION

of the apparatus, which is diagrammed in the sketch, Fig. 2. The compressed air is taken from the regular service lines for pneumatic tools (90-lb. pressure) through an adjustable pressure-reducing valve. An air receiver, consisting of an ordinary domestic hot-water tank, is tapped on the line near this point to absorb pulsations in the air supply. The bushings at both

FIG. 2. SKETCH OF PIPING FOR EXPERIMENTAL PULVERIZED-COAL BURNER

mixing chamber and burner are drilled with a number of small holes so that auxiliary air may be drawn in as desirable. A helical screw is fixed in the line just before the mixing tee so that the whirling air supply may expand into a wide spray. In operation the mixture of air and coal is ignited by some burning waste until the muffle becomes hot enough to maintain the flame near the end of the 2-in. pipe sleeve.

This successful innovation was made by Mr. Howard Wright of the roasting department and Mr. William Erickson, engineer, working under the supervision of Mr. E. H. Hamilton, general superintendent.

Vernier Scales for reading decimal parts on graphic charts can readily be made on a tenth basis by applying the edge of a sheet of paper to the coordinates 10 and 4.58 and marking off the tens, and on a hundredth basis by using 100 and 1 as coordinates and marking off the intersections with the 100-lines. This is of use in accurately reading small scale charts.

## Atlantic City Meeting of the War Service Committees

Several Thousand Prominent Business Men Representing Three Hundred and Eighty Industries Hear Addresses on Reconstruction, Discuss and Pass Resolutions—Plan to Expand Scope of the Chamber of Commerce of the United States

THE meeting held under the auspices of the Chamber of Commerce of the United States Dec. 3 to 6 was a memorable occasion, and if we were asked to describe it we should say it was distinctly characterized by sanity, breadth of view and generosity. The plan was excellent, and the details, although rather jumbled at first, were brought into order by the second day. The general meetings held in the great hall of Young's Pier were attended to capacity. It is said that the place will seat 6000 persons comfortably, but there was not even standing room for all those who desired to attend these general meetings.

### ADDRESS OF PRESIDENT WHEELER

The addresses were remarkable contributions to the constructive thought of the day. Mr. Harry A. Wheeler, President of the Chamber of Commerce of the United States, made the first of these on Wednesday and treated more particularly of reconstruction, pointing out certain principles which must be applied if victory is to be secure in the fulfillment of those aims for which our men have fought. He pointed out how diplomacy needs the aid of men of business in its councils, more particularly in the problems of readjustment. Already, he said, whisperers, trouble-breeders and jugglers with words and reputations are turning their eyes to the unsavory diplomacy of the past and are intimating jealousies and jockeyings for position for which there should be no hearing at all among men of good will. He urged a more enlightened diplomacy which shall be free from secrecy and open to the judgment of public opinion.

He proposed an international plan for rationing raw materials so that nations which are not fortunate enough to possess them may be free to develop their science and their arts. He urged a live-and-let-live policy for the whole world. We must make the most of available tonnage and he insisted that if those nations which have the power to contribute to the reconstruction of countries and peoples stricken by the devastation of war do not bear these obligations in mind, then hardships and difficulties will be inordinately prolonged.

On Nov. 23 last he addressed a letter to the President asking if it would not be helpful if American industry should name a committee, informed in the basic industries of the country, to be present in France during the meetings of the Peace Conference and available for counsel in negotiations which bear directly upon commerce and industry. The President replied that frankly he did not know what message to contribute to the Atlantic City meeting, but that we should all take counsel and apply the wisest action to circumstances as they arise.

In its final resolutions the Conference concluded that a body of such competent men of large vision and generous impulses should be present. Other problems con-

sidered were subjects of extended debate at the various group meetings and found expression in the resolutions adopted at the final session.

### THE SECRETARY OF COMMERCE

On Wednesday Secretary Redfield made an earnest appeal for the application of science to industry. He gave a brief outline of the extraordinary activities of the Bureau of Standards and extended a cordial welcome to American business men to enter its open portals. He outlined the work of the Department of Commerce in the extension of foreign trade. The agents of the Government engaged in this service, he said, were required to be intimately familiar with the subjects which they are sent abroad to investigate and are required to have an easy reading, writing and speaking knowledge of the language of each country to which they are sent. He hoped that greater appropriations for an increase in the number of these useful agents of trade may become available.

### MR. CHARLES M. SCHWAB

Mr. Charles M. Schwab, Director General of the United States Emergency Fleet Corporation, first got his six or seven thousand auditors into good humor and then proceeded to discuss what he regarded as the most immediate problem before us in matters of reconstruction, which has to do with labor. We are all in the same boat, he declared; time was when capital tried to be the sole ruling factor in affairs, and labor has done the same thing. It cannot succeed. He recalled with no little humor the efforts made by trusts to control prices and profits without much consideration of the consumer, and he painted the consequences in lively colors. In regard to the Fleet Corporation, he said that when he undertook the direction of its affairs, he knew it would succeed if only American labor would back him up, and he was proud to say that American labor had done this very thing. Of course there had been troubles; it is impossible to gather in such a vast army of workers without having some whose vision of the general welfare is blinded by selfishness. But in the main they had been gloriously loyal to their country's call, and he could not put too much emphasis upon that fact. His only reason for leaving the post at the head of the Fleet Corporation was to return to the 170,000 employees under him at Bethlehem and elsewhere to provide for the best pay and the best conditions that may be brought about. He is a firm believer in organization within the works or the corporation and in the maximum of safeguarding every man's rights as well as his life and his liberty.

### PRESIDENT FARRELL OF THE U. S. STEEL CORPORATION

On Dec. 5 Mr. Farrell was unable to get to Atlantic City and his address was read in his absence. It had to do with foreign trade, and he said that it had grown

to such proportions that it was no longer necessary to convince manufacturers to enter it, but that our present task was rather to devise and guide. So devastating, however, has the war been that we cannot expect export trade to flourish unless we provide capital in those countries where we hope that our business may prosper. We must enter into their industrial life, engage in enterprises with them and thus create out of their resources the new wealth from which will come our pay. The advent of women into industry has been so great and so general that he doubted whether there would be as marked a shortage of industrial labor in the near future, even in war-devastated countries, as has been anticipated.

MR. JOHN D. ROCKEFELLER, JR.

Mr. John D. Rockefeller, Jr., spoke at the same meeting as that at which Mr. Farrell's paper was read, taking for his subject "Representation in Industry." He said that Capital, Management, Labor and the Community were the four parties to industry and that each was entitled to representation. Capital is represented by stockholders and is usually regarded as including management, but this is a serious error. The function of management is different and it is represented by technical skill and managerial experience. Labor is represented by the employees, but its contribution, unlike that of capital, is not detachable from the one making it, for it is his physical effort, his strength, his life. The community contributes the maintenance of law and order, the agencies of transportation and communication and many other services of prime importance. And the community consumes the product. Selfishness is not to be tolerated. Whether men work with brain or with brawn they have the same cravings, the same aspirations, the same hatreds and the same capacity for suffering and enjoyment. He insisted that we must organize a new order of things and provide some plan of co-operation which will insure to all concerned adequate representation, an opportunity to earn a fair wage under proper working and living conditions with such restrictions as to hours as will leave time for recreation and the development of the higher things of life as well as time to eat and to sleep.

He outlined a method which he favors which provides for the representation of labor and for appeals from decisions, and he gave a number of instances in which the plan is in successful operation. In conclusion he stated what he called his labor creed, which was included in a short form as the sense of the convention by a resolution unanimously adopted at the final meeting on Friday.

MR. PAUL M. WARBURG

Mr. Warburg, until lately a member of the Federal Reserve Board, made the last address on Friday. He recommended that to enable the United States to take its place as a foremost power in the commercial and financial world and to be fully equipped, the Capital Issues Committee and the War Finance Committee be continued. Government responsibility and influence in industry will tend to elevate business, but it presents the danger, he said, unless carefully guarded in form and scope, of corrupting and debauching the government itself. In the call for the continuation of these com-

mittees he added there is no challenge to England. He is certain England will retain her logical and traditional position as a world center for commerce and finance. Germany's position as an international banker will have to be considered as vacated for some time to come, but England, the United States and soon France as well will become partners rather than competitors; not partners in a close corporation to the exclusion of others, but rather in an establishment wide open to any respectable associate wishing to enter.

#### NINETY SPEECHES

As announced in our previous issues, the three hundred and eighty-odd war committees were grouped into thirty-six sections called related groups, which met in various places on the evening of Dec. 4. At each of these meetings there were addresses and here also resolutions were discussed which were brought in from the War Service Committees or offered from the floor. All resolutions passed were turned over to the corresponding unit of the ten major groups into which the thirty-six were consolidated and which met on the following (Thursday) afternoon at 2:30 and evening at 8 o'clock. Here again addresses were delivered, but our readers will understand why we cannot print these ninety addresses despite their leading importance to the industries involved. With apologies for our shortcomings in this respect we shall add a few notes from the addresses delivered before the committees on chemicals.

#### SECRETARY REDFIELD AGAIN

Chairman Henry Howard of Boston, who presided over the deliberations of Group 26, induced Secretary Redfield to add to his remarks of the same day in the Great Hall. Mr. Redfield's impression of the prospective status of the German chemical industry is that it will be far less favorable than before the war. That the country is evidently pretty well used up was indicated by the sore complaint that arose at the armistice demand for a certain number of locomotives and cars. The purpose was merely to restore the locomotives and cars taken from Belgium and France by the Germans. If the complaint is well founded that the act leaves them without the means of transportation, then the deduction is reasonable that the German railway system is used up as to equipment and that that of French and Belgian origin was used for replacement. He believes that the cost of production in Germany will increase more in proportion than it will here. Returning to the subject of scientific development in this country, he added the note that on the second day of President Wilson's first administration it was agreed between the President and himself that no man in the scientific service of the Government should be removed or appointed for political reasons, and that the agreement has been kept.

MR. W. D. HUNTINGTON

Mr. W. D. Huntington of the Davison Chemical Works, Baltimore, gave some information of the acid industry and its status. In 1914 we produced 4,200,000 tons of sulphuric acid of 50 deg. B. In 1917 this had increased to 8,300,000, and if the war had continued four or five months longer we should have been producing at the rate of 9,600,000 tons annually. The out-

look is that the only part of the country where any congestion of acid may occur will be in the Northeast. The rated capacity of plants outside of those owned by the Government is 6,200,000 tons, and in the South the fertilizer industry will absorb the output of the two great privately owned munition plants that are located there. The Government plants are closing. In the Northeast it may be necessary to reduce production to 70 per cent of capacity for awhile.

The great stocks of nitrate and sulphur at the Government plants should not be thrown upon the market, and he was glad to say that steps are being taken to avoid this very thing. The sulphur, for instance, will be taken in charge by the sulphur companies and distributed by them. The Government is anxious to dispose of stocks in such a manner as to do so to the greatest advantage and with the least hindrance to trade. In the discussion which followed Mr. Charles H. McDowell expressed the opinion that the consumption of acid will be at least 1,000,000 tons more than in 1914 and that an increase of 1,500,000 tons would be a closer guess.

#### MR. A. W. HAWKES

Mr. A. W. Hawkes, Vice President of the General Chemical Company, followed with the belief that increased consumption of sulphuric acid will take up the slack. The best way, in his opinion, is to play a waiting game for the next ninety days. In the meantime, he said, antiquated plants are being discontinued, and others, with the stress of extreme production removed, are being put into better operating condition.

#### DR. J. MERRITT MATTHEWS

Dr. J. Merritt Matthews read a paper on "Safeguarding the Dye Industry," in which he described the proposed British method of prohibiting the import of dyes made within the kingdom and requiring that a license be obtained from a special commission for every importation of foreign colors. The commission is to have very great power, for it is assumed that it will also grant licenses for importations to supply needs in excess of that which is made at home. Despite the many objections that may be raised against it, Dr. Matthews believes it to be the best method available to control the situation. If the licensing system should not be adopted, he recommended that both intermediates and dyes have equal protection to avoid the establishment of foreign houses to put through the last and simplest processes in making dyes from materials almost but not quite finished, which under the present law they could import under one-half the tax which the finished product pays.

#### DR. W. H. NICHOLS

Major Group 7 included all the junior groups related to it, and it met Thursday afternoon and evening under the chairmanship of Mr. Horace Bowker. The afternoon speaker was Dr. William H. Nichols, President of the American Chemical Society and Chairman of the Board of the General Chemical Co.

His address was an appeal to prevent the dye industry, which has taken such an effort to establish, to lapse, because it is so closely bound up with the development of chemistry and more particularly with chemical research and it contributes so much to that kind of pre-

paredness for war which is the best defense against it. He called special attention to the fact that the industry has not yet matured with us. To prove it he took the figures lately issued by the Tariff Commission giving the number of concerns engaged in making dyes and intermediates and the number of men engaged, and he divided the total men employed into the tonnage. Then he made a similar computation of the latest available

DR. WILLIAM H. NICHOLS

German data, and the showing was very unfavorable to the present American dye industry compared with that which formerly obtained in Germany. In other words, taking the entire industry of the country and including all engaged in it, the yields or finished product per man employed are still inadequate to meet German competition. This should involve no reflection upon American chemists. The war problem was to produce the things needed at any cost, and in many cases this was done. Now in organic syntheses there are often a number of ways to make a thing and it takes time and patience and chemical scholarship to develop the best method and then to nurse it along to maximum efficiency. This very development is in process now wherever sound chemical control is coupled with scholarly research, but results are not to be reached over night. Dr. Nichols had no definite measures to propose as to the specific means of conserving the industry, but he expressed his firm conviction that if our chemists have a fair chance for a reasonable time, without outside interference, we can lead the world in making dyes. He held to this without being frightened over the fact that the Swiss works are all unified, that the German works have joined in a Cartel, and that in England, France, Italy and Japan direct action has been taken by various steps such as prohibition of imports or guarantees of dividends to assure the maintenance of the industry in those countries.

At the evening session Mr. Charles H. McDowell of the Chemicals Division of the War Industries Board gave an interesting and illuminating outline of the problems which the Committee had to meet. He expressed the opinion that very cheap producer gas power

had been developed in Germany and he went into detail in regard to the nitrate situation from the beginning. Toluene production has increased from 500,000 gallons a year in 1914 to the rate of 24,000,000 gallons a year now. The alkali industry has increased in great measure, but he believed that the closing down of the Government electrolytic plants would avoid the production of excess alkali. The War Board, he said, tried to be constructive in its destruction and found many substitutes for materials that were required, a considerable number of which have entered into permanent use. The oxygen output has increased 1400 per cent since 1914 and 92 per cent of the whole is distilled from liquid air. He gave a long list of contributions made by the Mellon Institute of Industrial Research at Pittsburgh to the War Board and he urged upon industry the increase of technically trained men in its personnel. In regard to potash he doubted if Germany will be able to produce as cheaply as before the war, and he regarded as fair possibilities the outlook for about 30,000 tons from blast furnaces and 50,000 tons from the cement industry (on a  $K_2O$  basis) in this country under normal conditions. The cost at Searles Lake cannot be determined until larger quantities are produced, and the Georgia shales, containing 6 to 8 per cent of  $K_2O$ , he believed also to be a promising source of supply. In conclusion he noted the greatly increased team work throughout chemical industry as a result of the common experience of its many leaders who have given their time to the War Industries Board.

#### FEW FREAK RESOLUTIONS OFFERED

It stands to reason that in such a vast assemblage of men, all sorts and kinds of resolutions should be proposed. They always are, and they were this time. Sometimes the myopics (who constitute the short-sighted brotherhood) would line up at the back of the room at group meetings and vote through resolutions that had no place there,—and sometimes they failed in the attempt. There were some rather amusing incidents in this connection. The laundry owners, for instance, undertook to have it declared to be in the interest of the general welfare that articles washed for the retail trade should not be deliverable until four days after the pick-up. The motion was lost. The surgical instrument makers, on the other hand, firm in the faith that all things should work together for their good, managed to put through a demand at a group meeting that the United States Government should not dispose of any surgical instruments now in its possession until they become obsolete, "in order to be at all times prepared for war." There were, however, surprisingly few efforts of this sort, and excellent provision was made for them. After matters had been threshed over first at the related group meetings and again at the major group meetings, all resolutions were sent to the Clearance Committee, which worked all night, referred all piffle and unbaked ideas back to the Executive Committee of the Chamber of Commerce and by their supremely able drafting of consolidated ideas, presented those which follow in substance at the general meeting which closed the conference on Friday.

All of their proposals were adopted with nearly complete unanimity. Lack of space makes certain abridgements necessary.

### The Resolutions Adopted

*Cancellation of War Contracts:*—It is in the public interest that all war orders placed by any contracting agency of the Government and accepted in good faith, whether formally and regularly executed or not, should, upon cancellation by such contracting agency, be promptly and equitably adjusted and satisfied as if every formality had been observed, and when so adjusted the amount ascertained to be due by the Government should be promptly paid to the end that these funds may be utilized by the industries of the country to speed their transition from a war to a peace basis.

If it should be ascertained that legislation is necessary or desirable to accomplish this end, Congress should forthwith enact such legislation.

Officials dealing with questions of adjustment on account of war orders must necessarily be familiar with all the conditions affecting the order. It will greatly promote expedition and the interests of both the Government and private enterprise for the officials who made the contracts to remain in the Government service to participate in the readjustments.

*Surplus Government Supplies:*—Under date of Nov. 29, 1918, the Secretary of War issued a public statement, i.e., "To prevent too violent dislocation of industry from the standpoint of both employee and employer, accumulation by the War Department of either raw material or finished product will be distributed when and where liquidation of such supplies will least interfere with the return of industry to a normal condition." Such action would seem to insure the stability of the industries affected, which fully appreciate this liberal position.

Therefore the War Service Committee of American Industries hereby tender to the War Department their services for their respective industries for the purpose of advising with and assisting the War Department in the disposition of such materials.

*Removal of Restrictions of Industry:*—It is in the public interest that all war regulations of industry should be revoked and all war restrictions on industry should be removed as speedily as practicable, save such industries as are engaged in the production, preparation or distribution of foods, feeds and fuel, and such last named group of industries should be freed from war regulations and restrictions as early as consistent with the welfare of this nation and of the Allies.

*Pivotal Industries:*—Conditions brought upon us by the European war at its beginning, as well as our national necessities after we entered the war, made it of the highest importance that a number of industries should at once be developed in the United States. Large investments, both of capital and skill, have since been placed in these enterprises. Upon the production of some of them, relatively small in themselves, the continuation of some of our largest industries has depended. Some of the recently developed industries have national importance in fields much broader than the markets of their products; for they may serve, for example, to promote scientific research, which will add to national efficiency, resources and wealth in many distinct ways.

It becomes essential, therefore, that the Government should at once proceed to ascertain the industries which have been developed during the European war and ascertain those the maintenance of which are indispensable for the safety of our industrial structure and our military establishment.

When these pivotal industries have been ascertained, means suitable in view of their nature and situations should at once be provided for their encouragement and preservation.

*Industrial Co-operation:*—The war has demonstrated that through industrial co-operation great economies may be achieved, waste eliminated and efficiency increased. The nation should not forget, but rather should capitalize these lessons by adapting effective war practices to peace conditions through permitting reasonable co-operation between units of industry under appropriate Federal supervision. It is in the public interest that reasonable trade agreements

should be entered into, but the failure of the Government to either clearly define the dividing line between those agreements which are and those who are not in unreasonable restraint of commerce, or to provide an agency to speak for it on application of those proposing to enter into such agreement, in effect restricts wholesome co-operation and deprives both industry and the general public of its benefits. The conditions incident to the period of readjustment render it imperative that all obstacles to reasonable co-operation be immediately removed through appropriate legislation.

**Federal Trade Commission.**—The Federal Trade Commission was advocated by the President and was created as an agency to make the administrations of our trust legislation explicit and intelligible, and to provide "the advice, the definite guidance and information" which business enterprises require. The normal importance of the Commission's task is now tremendously increased by the imperative need for whole-hearted and systematic co-operation between the Government and industry especially during the readjustment period and suggests the desirability of the two existing vacancies in the Commission's membership being promptly filled with able men of broad business experience and clear vision prepared to assist actively in discharging these tasks along constructive lines.

**Industrial Relations.**—The Convention heartily indorses in letter and spirit the principles of the industrial creed so clearly and forcibly stated in the paper read to it Thursday morning by Mr. John D. Rockefeller, Jr., and urges upon all units of industry where they may not now be employed the application of such principles.

Without approving or rejecting his particular plan or machinery, the principles advanced by Mr. Rockefeller are as follows:

1. Labor and capital are partners, not enemies; their interests are common interests, not opposed, and neither can attain the fullest measure of prosperity at the expense of the other, but only in association with the other.

2. The purpose of industry is quite as much to advance social well-being as material well-being and in the pursuit of that purpose the interests of the community should be carefully considered, the well-being of the employees as respects living and working conditions should be fully guarded, management should be adequately recognized and capital should be justly compensated, and failure in any of these particulars means loss to all.

3. Every man is entitled to an opportunity to earn a living, to fair wages, to reasonable hours of work and proper working conditions, to a decent home, to the opportunity to play, to learn, to worship, and to love, as well as to toil, and the responsibility rests as heavily upon industry as upon government or society to see that these conditions and opportunities prevail.

4. Industry, efficiency and initiative, wherever found, should be encouraged and adequately rewarded, and indolence, indifference and restriction of production should be discountenanced.

5. The provision of adequate means for uncovering grievances and promptly adjusting them is of fundamental importance to the successful conduct of industry.

6. The most potent measure in bringing about industrial harmony and prosperity is adequate representation of the parties in interest; existing forms of representation should be carefully studied and availed of in so far as they may be found to have merit and be adaptable to the peculiar conditions in the various industries.

7. The application of right principles never fails to affect right relations; the letter killeth and the spirit maketh alive; forms are wholly secondary, while attitude and spirit are all important, and only as the parties in industry are animated by the spirit of fair play, justice to all and brotherhood will any plans which they may mutually work out succeed.

8. That man renders the greatest social service who so co-operates in the organization of industry as to afford to the largest number of men the greatest opportunity for self-development and the enjoyment by every man of those benefits which his own work adds to the wealth of civilization.

**Relocation of Labor.**—The conversion of the industry of

the country from a peace basis to a war basis involved a general and important dislocation of labor. This movement was gradual. The end of the war involves a much more rapid change in industry; while there will be a great demand for labor to meet the foreign and domestic requirements, there may be for a time in special places a temporary condition of unemployment.

In the new relations of industry to labor we conceive it to be incumbent upon the community affected promptly to meet such conditions.

**Public Works.**—The development of public works of every sort, as recommended by the President, should promptly be resumed, in order that opportunities of employment may be created for unskilled labor.

**Taxation.**—The cessation of hostilities brings to business interests a feeling of deep concern in the matter of taxation. The problems of readjustment are made more difficult through inequalities in the present law.

We believe, therefore, that in the consideration of amendments to the present act, or the passage of new revenue legislation, the Congress should give most careful consideration to the views expressed by organizations of commerce and industry. Ability to pay, inventory values and proper reserves, together with careful survey of the amount of revenue required under the new conditions, are matters of vital importance to business interests of the nation during this readjustment period.

**Inventories.**—We urge that Congress should give careful consideration to the grave menace now facing all industry due to the fact that both raw materials and finished goods are carried in full measure to meet the extraordinary requirements of the Government and of the people, and that in large part the stocks have been acquired at abnormal cost and are therefore carried into inventories at inflated values, thereby showing apparent profits which have not been realized, and which probably will never be fully realized. These are largely bookkeeping or "paper" profits, and should not be used as a basis for taxation.

We therefore recommend that any tax law shall provide that during present conditions the taxpayer shall be allowed to make a deduction from his apparent profit by way of a reserve for subsequent shrinkage in merchandise values.

We believe that the interests of the Government can be protected against abuse of this privilege by the fixing of a maximum percentage of deduction to be allowed and by the use of proper methods of inspection and appraisal.

**Water Powers.**—Industrial activity is dependent upon the available supply of power. A bill which would affect the development of hydro-electric power upon waterways and lands which are subject to Federal jurisdiction is now before a committee of conference between the two houses of Congress. It is important in the public interest that Federal legislation on this subject should be enacted without further delay. We accordingly urge that the conference committee arrive at an acceptable form of legislation in season for enactment at this session of Congress.

**European Commission.**—The business men of the United States, having devoted their energies and resources toward the winning of the war, regardless of sacrifices or burdens, in support of the principles for which this country fought, appreciate the necessity of continuance of unremitting effort in order that the world may be restored to normal conditions as quickly as possible and the blessings of peace brought to all peoples.

In the accomplishment of these results the highest efficiency of the great commercial and industrial powers of our own country and that of the Allied nations will be developed only through co-operative effort and common counsel.

In order, therefore, to contribute to the fullest toward the prompt solution of the problem presented, the Chamber of Commerce of the United States is requested to enlist the co-operation of national bodies devoted to the extension and promotion of American commerce and particularly foreign trade, in the appointment of a commission representative of American business, which shall proceed without delay to Europe and establish machinery for the following purposes:

1. To study at first hand the reconstruction needs of European countries in conjunction with business men of these nations in order to advise the business men of the

United States as to how they may be most helpful in meeting the necessities of Europe and caring for the interests of American industry and commerce.

2. To be available to the peace delegates of the United States for any needed information which they may be able to present or for any other aid which may be given by the business men of the United States through the medium of such a commission.

The Chamber of Commerce of the United States also is requested to appoint members of the Commission to represent the business men of the United States at the forthcoming meeting of the Permanent Committees of the International Congress of Chambers of Commerce.

**Markets for Foreign Trade.**—We strongly urge upon our Government the vital necessity of encouraging and developing our foreign trade through all appropriate means possible, in order that the production of industry may afford employment to wage earners and prosperity to the nation.

**South American Relations.**—It has long been the policy of this nation to cultivate relations of close sympathy with the nations of the Western Hemisphere as expressed in the Monroe Doctrine. We believe that these relations should be supplemented and strengthened by a vigorous development of our commercial and financial associations with our neighbors of North and South America.

The Government's control of shipping should be brought to the accomplishment of this purpose as soon as it is consistent with other urgent needs, and the work of the Pan-American Union should be continued and broadened in scope.

**Property Rights in Mexico.**—By provisions in a constitution adopted while much of the country was engaged in civil strife, and through subsequent legislation, Mexican authorities have threatened rights acquired by Americans in good faith, especially in minerals, including petroleum. Against threatened confiscation the American Government made formal protests. The attitude taken by the American Government is heartily commended as in accordance with obvious justice.

**Education for Foreign Commerce.**—In the larger opportunities which are to be opened to American business men to play a part in the international commerce of the world the need will be felt for more men who are trained to a knowledge and understanding of the language, the business methods and the habits of thought of foreign lands. Complete success can only come to those who succeed in putting themselves into full accord and sympathy with the peoples with whom they are to deal.

We urge upon our industrialists that they take steps to provide opportunities to young men to obtain an education in the practices of overseas commerce and finance and in the practical use of foreign languages.

We call the attention of the various departments of Government and to educators to the importance of this matter and ask that special efforts be made to supplement the valuable work already done and to open up every facility to the furtherance of a successful prosecution of this educational work.

**Forest Products Laboratories.**—The Forest Products Laboratories, of the United States Forest Service, have rendered valuable service through scientific investigation of the physical properties of American woods and their adaptability for structural, industrial and ornamental usage. It is of great importance to American industry that the Government should extend and adequately maintain the work of the Forest Products Laboratories.

**Cost Accounting.**—It is the sense of this Convention that uniform cost accounting should be adopted by industries.

Other resolutions favor the return of railways to their owners under proper conditions, oppose Government operation of telephones, telegraphs and cables, favor the development of the merchant marine, the amplification of port facilities, the proper study by Congress of public utilities, the generous provision of raw materials to our Allies for reconstruction, the extension of scope of the Council and Executive Committee of the Chamber of Commerce, and resolutions of appreciation of the work of the speakers, the committees and the Associated Business Papers for their daily newspaper.

## Institute of Chemical Engineers Chicago, Jan. 15-18

THE secretary of the Institute, Dr. John C. Olsen, Polytechnic Institute, Brooklyn, N. Y., announces this tentative program for the winter meeting:

"What Is Going to Be Done by the Tariff Commission on the Question Relative to the Chemical Industry?" Dr. Grinnell Jones, U. S. Tariff Commission, Washington, D. C.

"United States Dye Industry," Dr. L. J. Matos and Dr. L. C. Jones, National Aniline Co., New York.

"Reinforced Concrete Tanks for Storing Ammoniacal Liquors," Dr. F. W. Frerichs, St. Louis, Mo.

"Reconstruction Aspects of Some Chemical Industries in the United States," Dr. Edward Gudeman, Chicago, Ill.

"Some Wild Engineering," Dr. David Wesson, Montclair, N. J.

Excursions will be made to the plants of the Corn Products Co., Argo, Ill., Lindsay Light Co. and Underwriters Laboratories in Chicago, Standard Oil Co., Whiting, Ind., and the Newport Hydrocarbon Co., Milwaukee, Wis.

The following letter has been sent to the chemical manufacturers of the United States:

"GENTLEMEN:—On Jan. 15 to 18, 1919, the annual meeting of the American Institute of Chemical Engineers will take place in Chicago. The chemical manufacturers of the United States are invited to send representatives to discuss the subject of the maintenance and preservation of our chemical industries.

"There are some who believe that a high protective tariff is all that is necessary to preserve the chemical industries. There are others who believe that only the newer chemical industries should be fostered, but it is the belief of your committee that the chemical industry of the United States must be carefully assisted not through any one particular means but through various methods which your committee briefly outlines.

"It is impossible to forecast the future, but if Germany fosters or otherwise subsidizes its chemical industries by means of specially low freight rates and transportation facilities, or if other countries pursue such a policy, the American chemical industries will be at a great disadvantage as far as export trade is concerned.

"Of course it is not to be presumed that the chemical industries will ask governmental assistance in those things which the chemical industries are competent to take care of themselves. This phase should also be presented.

"In 1919 a large amount of shipping will leave these ports filled with the necessities of life, such as food, agricultural implements and metals, and in preference to coming back in ballast, they may take freight at such low rates, and Germany may be willing to sell the materials it has on hand at such ruinous figures in order to obtain real money, that for a time paralysis of our industries may ensue.

"Another condition that always confronts manufacturers is unnecessary and undue competition, and our laws prevent co-operation excepting in cases of export. These are only a few of the conditions which must be manfully met and solved, and at the January meeting of the Institute the fullest discussion is invited, and the aid of our congress will be invoked.

"Will you be good enough to signify to the Secretary whether you will send a representative to attend this meeting. Respectfully submitted,

L. H. Baekeland,  
Maximilian Toch,

"G. W. THOMPSON,  
"President."

Chairman, Committee of Maintenance and Protection of Our Chemical Industries.

# Aluminium-Manufacturing Processes Used in Europe\*

Historical Review of Researches and Commercial Developments—Refining of Raw Materials—Description of Bauxites Used and Processes for Obtaining Pure Alumina—Manufacture, Consumption and Requirements for Electrodes—Information About Operating

By O. NISSEN

IN 1811 Sir Humphry Davy produced an alloy of iron and aluminium by using an iron bar as the cathode. Thirteen years afterward Oersted is said to have produced the metal by heating aluminium chloride with potassium amalgam. Wohler in 1827 succeeded in producing it simply by reducing aluminium chloride with metallic potassium. As the materials were not pure and on account of the volatility of the chloride, the reaction was carried out at a low temperature. Up to 1845 Wohler had been able to produce only small particles of the metal, about the size of a pinhead. In 1854 Bunsen obtained aluminium for the first time by the electrolysis of aluminium-sodium chlorides, but electrolytic processes could not be of any practical importance at that time on account of the non-existence of large sources of electric current. Henry Sainte-Claire Deville developed the chemical reduction process after 1854 and with the help of Napoleon III a factory was built at Javelle. A few bars of aluminium were exhibited at the Paris Exposition in 1855 which attracted a great deal of attention. Deville conducted aluminium chloride vapor over incandescent potassium and had purer materials than Wohler. In place of potassium, Deville also used the cheaper sodium, and later he worked with aluminium-sodium chloride, which is less hygroscopic and more stable than aluminium chloride.

When in 1854 cryolite, the double fluoride of aluminium and sodium, was brought for the first time from Greenland to Europe, Dr. H. Percy produced aluminium from it by reduction with metallic sodium. At the same time and independently, H. Rose made the same experiment, and in 1855 he was the first one to produce aluminium by electrolysis of cryolite, when he was endeavoring to electroplate other metals with aluminium. Rose also used synthetic cryolite, and he reported: "This synthetic cryolite, as well as the natural, gives aluminium when reduced with sodium. Aluminium is also produced under the influence of the electric current, but not when alumina is dissolved in aluminium fluoride alone." Rose determined that cryolite, which is easy to pulverize and not hygroscopic or volatile, gave better results than aluminium chlorides or their combinations with chlorides of the alkali metals. Bunsen and Deville experimented in 1856 on the electrolysis of molten cryolite, but could not obtain the required electric current.

Chemical plants were built at Paris and Salindre. Th. Bell established a plant using Deville's process at Washington-on-Tyne in England. He also experimented with the electrolytic process. These plants were worked for about thirty years without material changes, but later magnesium was used as the reducing agent instead of sodium.

M. Heroult in 1887 constructed a practical electric reduction furnace for the commercial manufacture of aluminium by electrolysis, using alumina dissolved in molten cryolite. The fundamental principles of the furnace were chiefly those suggested thirty years previously by Bunsen and the electrolysis of the alumina

FIG. 1. HEROULT'S FURNACE

dissolved in cryolite was well known to Deville and others. The only novel feature, as was pointed out, was that the current was used both for the reduction of the aluminium and for heating the furnace, while before it had been the practice to heat the furnace externally by means of combustion. Bradley obtained a patent in America on just this idea.

Heroult's furnace, Fig. 1, consisted of an iron casing lined with carbon bricks. The current was introduced through a bundle of carbon anodes which could be raised or lowered by means of a chain. The total cross-section of the anode was 30 x 30 sq.cm. and the length 1.2 m. The bath occupied a space of 50 x 30 sq.cm., the inside height being 60 cm. The electric current varied from 3000 to 4000 amperes and was supplied by a generator at from 13 to 14 volts. The current passed through the molten cryolite, in which the alumina was dissolved, down to the casing which comprised the cathode. The alumina was decomposed and the aluminium settling at

\*Translated from *Teknisk Tidsskrift*, August, 1917.

the bottom was drawn off, while the oxygen liberated, in contact with the anode, combined with the carbon to form carbon monoxide, which is immediately burned, forming carbon dioxide on contact with the air. The carbon anodes are in this manner gradually used up. The raw materials were supplied to the furnace through openings in the fireproof cover. Heroult produced aluminium in large quantities and it is unquestionably to him that the credit belongs for having developed the electrolytic method so that it became of practical importance in France.

In Calypso, Minet experimented with lowering the temperature of the bath. He used aluminium fluoride with 60 per cent sodium chloride and also cryolite with 50 to 80 per cent salt. Minet's furnace, Fig. 2, has both the anode and cathode suspended in the bath; this is, however, not good practice. It reminds one of Bunsen's experimental furnace, Fig. 3. Hall experimented in America on adding to the cryolite, which was mixed with alumina, potassium, sodium, lithium, chloride and also calcium fluoride.

Following the Bucherer patented process, it is said that the Aluminium Industries Co. in Neuhausen carried out successful experiments on electrolyzing aluminium sulphide,  $Al_2S_3$ . The furnace voltage was very low—5 volts—and the metal pure. The sulphur was

FIG. 2. MINET'S FURNACE

FIG. 3. BUNSEN'S FURNACE

condensed and used again for producing new aluminium sulphide. The production of the aluminium sulphide by heating alumina, carbon and sulphur requires so much heating that the process was too expensive. The process now generally used in Europe for manufacturing aluminium has been developed directly from Heroult's furnace, although the type now in use has been much enlarged and improved. Heroult died shortly before the war with Germany broke out.

The great future that was entertained in the minds of many for aluminium and its production is reflected in the fact that during the '90s a large number of patents were taken out, the majority being more or less valueless. According to some of these patents, aluminium should be produced by electrolysis of water solutions. This could, of course, not lead to any commercial results, as aluminium in *status nascenti* is hydrolyzed by water. Also, according to others of these patents, aluminium should be produced directly by reduction with carbon in electric arc furnaces or in electric resistance furnaces. However, at the reduction temperature of 2000 deg. C. mostly aluminium carbide was produced. If this problem could be solved and aluminium manufactured in large furnaces of several thousand

kilowatts instead of in the present electrolytic baths of about 150 kilowatts, it would, of course, be of immense value.

Cowles tried in America and at Milton in England to smelt aluminium and carbon in retorts, but the product which he obtained was valueless, as it contained too much carbide. His furnace, Fig. 4, was  $1\frac{1}{2} \times 1\frac{1}{2}$  m. and

FIG. 4. COWLES' FURNACE

$\frac{1}{2}$  m. high. Cowles did, however, produce aluminium alloys, and avoided thereby the formation of carbide.

Moissan, in an experimental furnace, Fig. 5, obtained aluminium with some carbide content and, besides, carbide and corundum crystals. He heated alumina and carbon in a carbon tube by means of an electric arc. Many chemists have worked with this reaction, but without practical result. To prevent carbide and oxidation formations Ruff and Giuliani suggested vacuum furnaces in which the reaction would take place around 1500 deg. C. Askenasy suggested just the opposite, i. e., pressure furnaces.

#### THE COMMERCIAL PRODUCTION OF ALUMINIUM

Only a few kg. of aluminium were produced during the first years succeeding 1854, and from 1863 to 1878 the yearly production did not exceed 2 kg.; from 1878 to 1888 between 10 and 40 tons were produced. The price was more than 1000 fr. per kg. at the beginning, but due to installation of Deville's and other processes it dropped to 300 and later to 100 fr. It was, however, not until the latter part of the '80s that the price fell to an economical level because the electrolytic plants in-

FIG. 5. MOISSAN'S FURNACE

creased the production so that in 1891 it amounted to 333 tons at a price of 4 fr. per kg.

From the diagram, Fig. 6, it is seen how rapidly the production increased. After 1893 the price dropped still more and was in 1900 or 1901 about 1.60 fr. per kg. On account of this drop the International Aluminum Syndicate was formed, the object of which was to en-

deavor to control the market and get better prices. La Société-Electrometallurgique Français des Froges, La Compagnie des Produits Chimiques d'Alais et de la Carmargue, Alluminum Industrie Gesellschaft Neuhausen, Pittsburgh Reduction Co. or the Aluminum Company of America and finally the British Aluminum Co. were the members of this syndicate. The production as well as the consumption of aluminium increased, and the price went up and reached 3.20 fr. per kg. in 1907.

FIG. 6. PRODUCTION AND PRICES

The over-production of the years following and the general business depression caused a violent drop in the price. English firms fought against bankruptcy, many plants were shut down, the syndicate was dissolved and the price dropped to 1 fr. per kg. The price, however, increased before the war to more than 2 fr. and all plants began operation again. A few even enlarged their facilities. A French syndicate was again formed in 1910, and it became international in 1913.

The yearly production before the war was 68,000 tons, divided as follows:

|                                        | Per Cent |
|----------------------------------------|----------|
| United States .....                    | 33       |
| Canada .....                           | 8½       |
| Switzerland, Germany and Austria ..... | 17½      |
| France .....                           | 26½      |
| England .....                          | 11       |
| Norway .....                           | 2½       |
| Italy .....                            | 1½       |

France and Switzerland were the countries that exported most aluminium, the amount for the last years before the war being 7000 to 8000 tons each. Germany, on the other hand, has imported aluminium; the statistics being 16,000 tons in 1912 and 12,500 tons in 1913.

It is difficult to obtain accurate information in regard to the aluminium production during the war. The prices have been abnormally high and a large number of new plants have been built, and contracts entered into for deliveries for several years after the war. Ger-

many and Russia will probably be the chief future consumers in the international market. It is possible that if all the plants which are building or contemplated are put in operation, the production after the war may be doubled, in which case we may figure on a yearly production of around 150,000 tons, divided as follows:

|                                        | Before the War<br>Per Cent<br>of 68,000 | After the War<br>Per Cent<br>of 150,000 |
|----------------------------------------|-----------------------------------------|-----------------------------------------|
| United States and Canada .....         | 41½                                     | 50                                      |
| Switzerland, Germany and Austria ..... | 17½                                     | 13                                      |
| France .....                           | 26½                                     | 13                                      |
| England .....                          | 11                                      | 8                                       |
| Norway .....                           | 2½                                      | 11½                                     |
| Italy .....                            | 1½                                      | 4½                                      |

For Norwegian factories it may be proportioned as follows:

|                  | Tons |
|------------------|------|
| Arendal .....    | 5000 |
| Tysedal .....    | 6000 |
| Vigeland .....   | 2000 |
| Stangfjord ..... | 600  |
| Hoyang .....     | 4000 |

These estimates have recently been made by a French engineer and indicate that France does not expect to keep up the hold it had on the aluminium industry before the war. When, however, the French saw the threatened competition of other countries, they immediately proceeded to build factories of their own in these countries. From a financial standpoint France will, therefore, continue to be the leader in the aluminium industry for some time to come. The French have been able to maintain this position, not only on account of their large bauxite deposits, but mainly due to the fact that they have been the pioneers of both the chemical and later the electrochemical aluminium industry. Not only have they tried to improve the methods of its production, but at the same time they have devoted just as much attention to finding new fields for its utilization. It may be predicted that, next to iron, aluminium will be the most important industrial metal.

These results could never have been obtained if it had not been realized from the beginning that an impure aluminium would have greatly discredited the product, and the problem has therefore all along been one of producing as pure a metal as possible.

#### METHODS OF REFINING RAW MATERIALS— ALUMINA FROM BAUXITE

At present there exists no satisfactory process for purifying metallic aluminium, and the only manner in which a pure product can be obtained is by the use of pure raw materials. This was clearly understood by Deville. The main raw materials for production of aluminium are alumina and carbon electrodes, and the obtaining of these with the required purity will be described in the following:

The alumina is produced by purifying bauxite, the red grade of which contains large amounts of impurities such as iron oxide and silica. According to the Deville-Pechiney process the bauxite is pulverized and mixed with anhydrous sodium carbonate in the ratio of 75 per cent bauxite and 25 per cent soda. The mixture is then heated two to three hours in a reverberatory furnace, whereby sodium aluminate is formed. This is separated from the iron oxide by leaching with warm water. The alumina is then precipitated from the extract solution by passing carbonic acid through the strong liquor, the carbonic acid being obtained from the

reverberatory furnace or lime calcining ovens. The process takes 5 to 6 hours at 70 deg. C. The precipitated alumina is then washed with clean water, filtered and dried and is then ready for the production of aluminium. The carbonated solution is evaporated and the soda recovered.

The Deville-Pechiney process is not economic as far as the fuel consumption is concerned and the Bayer method has superseded it. The operation of this is also somewhat simpler. The red bauxite is pulverized so as to pass through a screen of 5 mm. mesh and is cal-

much of the latter will cause a loss in alumina in that in the soda solution there is formed a non-soluble aluminium-sodium silicate of the approximate formula

In French bauxite of 61 per cent  $\text{Al}_2\text{O}_3$  and 3 per cent  $\text{SiO}_2$ , 5 per cent of the alumina is lost and the silica content in the final product will not exceed  $\frac{1}{4}$  per cent. Verge reaches the same favorable result with a bauxite having twice the content of silica, and uses only a temperature of 125 to 135 deg. C. in the autoclaves. Peniakoff produces alumina, similarly to Deville-Pechiney, in a furnace. He uses a 30 m. rotating kiln, slightly inclined, and reduces a mixture of bauxite and sodium sulphate with coal at a temperature of 1200 deg. C. The acid fumes after having been exposed to the air and steam are passed over salt, producing sodium sulphate. The hydrochloric acid which is formed thereby is recovered as a by-product. The process is thereafter identical to Bayer's.

White bauxite, which contains up to 25 per cent silica and up to about 5 per cent iron oxide, is purified in an entirely different manner from the red bauxite. It is pulverized and slightly heated so as to make it more porous. Warm sulphuric acid of 1.45 sp.gr. is thereafter cautiously added to the bauxite, and aluminium sulphate is formed under violent boiling. Steam and water are then added to reduce the sp.gr. to 1.2. The iron is dissolved as ferrous or ferric sulphate together with aluminium, and if the bauxite contains

FIG. 7. CALCINING FURNACE

cined in an oven such as is shown in Fig. 7, where the vegetation matter is burned off. The temperature is kept at 700 deg. C. and may not exceed 900 deg. C. as the higher burned alumina is less easily dissolved in the caustic solution. The calcining oven is about 10 m. long and has a diameter of about 1 m. The slope is 1 : 25 and the rotation is very slow. The lining consists of fireproof brick. The material is fed at the upper end of the upper tube and passes through the same in the opposite direction to the flame. The cooling takes place in the lower tube, which is smaller than the upper one. The bauxite is thereafter pulverized and sifted. The Verge process eliminates the preliminary treatment.

In the Bayer process the bauxite is now put into an autoclave and subjected to the action of a caustic soda solution of 1.45 sp.gr. It is heated with steam at 5 to 6 atmospheres pressure and agitated for two to three hours, the temperature being from 150 deg. to 160 deg. C. A solution of sodium aluminate is thus formed and is diluted to a sp.gr. of 1.23, from which the insoluble iron oxide is separated. The filtered sodium aluminate solution is then not treated, as in the Deville-Pechiney process, with carbon acid, but the diluted (1.23 sp.gr.) solution is agitated for 36 hours with a small quantity of freshly precipitated hydrate of alumina. This is done in autoclaves, such as shown in Fig. 8, having a diameter of about 4 m. and a height of about 6 m. About 70 per cent of the dissolved alumina is thus precipitated from the caustic and separated by filtration.

FIG. 8. AUTOCLAVE USED IN CAUSTIC PROCESS

magnesium, this is also dissolved. After it has been determined that no free sulphuric acid remains, the silica is separated.

The iron can be separated in different ways, either before solution, by oxalic acid, or after the decantation, with ferrocyanide of potassium or calcium sulphide. The aluminium sulphate solution is evaporated and the sulphate calcined in reverberatory furnaces.  $\text{SO}_2$  or  $\text{SO}_3$  is liberated during the heating and is again changed to sulphuric acid. The alumina which remains is non-hygroscopic and can be used directly for making aluminium. For satisfactory aluminium production the refined ore should contain at least 98 per cent  $\text{Al}_2\text{O}_3$ , not

The hydrated alumina is then filter-pressed under a pressure of 5 atmospheres, and the product is thereafter air-dried and calcined in tubular kilns, lined with magnesite brick. These kilns are about 6 m. long, have a diameter of 1.8 m. and are fired with gas. Even though the water is driven out at a low temperature, the alumina is heated to red heat at a temperature of about 1100 deg. C., as the alumina thereby becomes only slightly hygroscopic and can be used directly for production of aluminium. The diluted soda solution is again brought up to a sp.gr. of 1.45 in vacuum stills and can then be used again.

With both Deville's and Bayer's method it is necessary to use a bauxite with a low silica content, as too

more than 0.3 per cent  $\text{SiO}_2$  or 0.1 per cent  $\text{Fe}_2\text{O}_3$  and not more than 1 per cent  $\text{H}_2\text{O}$ .

Hall, in America, in connection with the Pittsburgh Reduction Co., has used a more direct method for purifying the bauxite. He uses an electric arc furnace constructed somewhat on the same principles as a carbide furnace. The bauxite is first calcined and mixed with 10 to 15 per cent carbon depending on its impurities. At the temperature of the electric furnace the silica, iron oxide and eventually the titanium oxide are reduced and also part of the alumina. There is formed a fluid alloy of iron, silicon, titanium and aluminium which sinks to the bottom and is drawn off. This alloy constitutes a valuable by-product. This simple method is reported to be feasible for the use with clay or aluminium silicates. The purified alumina will, however, not be as pure as by the chemical processes, and will not dissolve as readily in the cryolite bath.

Cowles and Kayser have also used the electric furnace for producing pure alumina. Kaolin, feldspar or clay was mixed with sodium chloride or calcium chloride in the ratio of 18 parts pure alumina to 23.4 parts salt, and in order to get the reaction to proceed more rapidly 15 per cent charcoal, produced from sawdust, was added. Briquets of this mixture to which some water was added were exposed to a temperature in the furnace corresponding to the temperature of volatilization of the salt. The oxidizing action of the steam prevents the sodium from escaping and there is formed a sodium-silica-alumina composition, and hydrochloric acid is evolved.  $2\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$  plus  $4\text{NaCl}$  plus water and carbon =  $2\text{SiO}$ ,  $\text{Al}_2\text{O}_3$ ,  $2\text{Na}_2\text{O}$  plus  $4\text{HCl}$  plus water and carbon oxide.

FIG. 9. SERPEK NITRIDE FURNACE

The hydrochloric acid is condensed to 18 deg. Baume and the salt as well as part of the aluminium chloride is recovered in chambers. After this, the mass is treated with lime in a revolving furnace and the following reaction takes place:

An excess of lime will form an insoluble calcium aluminate, while a shortage will cause part of the

insoluble sodium-silica-alumina composition to be unchanged. The alumina is separated from the soda solution and treated in the usual manner. The silica-lime composition can be used as a by-product for glass and cement manufacture. The hydrochloric acid can be used for producing a double chloride of aluminium and potassium by utilizing the feldspar.

Dr. Serpek, before the war, made very good progress with the AlN reaction in the production of both alumina and ammonia. He demonstrated the great affinity of aluminium for nitrogen at high temperatures. In conjunction with Badin, Dr. Serpek worked intensively

FIG. 10. HYDROFLUORIC ACID STILL

with large revolving furnaces or kilns, in which alumina was acted on by carbon and nitrogen at temperatures from 1600 to 1800 deg. C. By using a catalyst, such as iron and steam, it was possible to start the reaction even at 1300 deg. C. The furnace is lined with aluminium nitride, and the cross-section of an actual furnace is shown in Fig. 9. The electric resistance consists of carbon disks. There are eight columns, each 1.2 m. long, which are connected in series, and which take 10,000 amperes at 230 volts direct current. This gives a temperature of 1800 deg. C. in the furnace. The reaction is as follows:

When this aluminium nitride is treated in an autoclave with steam under pressure, it gives alumina and ammonia,

After the ammonia has been liberated the alumina can be used over again in the furnace. If, on the other hand, it is desired to use the alumina for producing aluminium, then the aluminium nitride is mixed with soda lye and the ammonia is liberated at 2 atmospheres pressure after from 2 to 2½ hours. The ammonia may be used for producing nitric acid, ammonium nitrate or ammonium sulphate.

The alumina is treated further according to the Bayer method. The treatment in the autoclaves is, however, simpler, as, according to Serpek, only 2 atmospheres pressure is required instead of 8 atm. The process is shorter and the concentration only 20 deg. B. instead of 40 deg. B. It is, therefore, claimed that the Bayer-nitride process costs only 63 fr. per ton of aluminium as compared to 126 fr. for the old Bayer process. This does not, however, include the cost of the bauxite. Besides this, ½ ton of nitrogen is fixed per kw.-year, cor-

responding to 2 tons of alumina. It will be of great interest to follow the results obtained by the aluminium-nitride process, and in this connection it may be of interest to learn that the Société Générale des Nitrures is also experimenting with ferro-aluminium, which has shown tendencies to combine with nitrogen, the reaction being exothermic. It is unfortunate that Badin has recently died. It is doubtful whether Dr. Serpek is continuing his experiments in Paris or St. Jean de Maurienne.

The subject of producing a pure alumina has been dealt with rather in detail, but it is absolutely essential that this part of the problem is thoroughly understood before one can have any hope of a satisfactory aluminium production. A number of prominent chemists are constantly working on this important problem.

#### CRYOLITE AND BATH FLUXES

Before proceeding to the electrode question, a few words may be said about the cryolite in which the alumina is dissolved. The natural cryolite, such as it is found at Tvigtut, Greenland, or at Miask, in the Urals, has the chemical formula  $\text{AlF}_3 \cdot 6\text{NaF}$ . The chief impurities are quartz, iron and lead, and it is mechanically purified by hand picking and with electro magnets. As obtained from the chemical factories at

shown in Fig. 10. The hydrofluoric acid causes bad burns and attacks the mucus membrane. One must therefore be extremely careful when working with it, and precautions such as wiping the hands with vaseline or the use of gas masks are to be recommended.

The fluorspar should not contain silica or silicates, as the formation of silicon-tetra-fluoride would result, which changes over to colloidal silicic acid, which renders the aluminium impure. The silica can, however, be removed by fluoride of potassium.

As the bath in the aluminium furnaces constantly loses fluorine, this must be replenished. If, however, fluorine was added in the form of cryolite, the bath would gradually be richer in sodium, which would go into the aluminium. Aluminium with only  $\frac{1}{100}$  per cent of sodium is brilliant, while a content of  $\frac{1}{10}$  per cent makes it dull and the utensils made therefrom will take on a dark color.

Aluminium fluoride,  $\text{AlF}_3$ , is therefore added from time to time to the bath, this being produced from hydrated alumina and hydrofluoric acid or aluminium sulphate and cryolite. Natural calcium fluoride, i.e., fluorspar, is also used.

#### MANUFACTURE OF CARBON ELECTRODES

The electrode production in an aluminium factory is of utmost importance inasmuch as the electrode consumption equals the weight of the aluminium produced. The electrodes must furthermore be of a special grade in that the ash content should not exceed 1 per cent. For an economical aluminium production, it is advisable to erect an electrode plant near the aluminium works, as in this manner it will be possible to use the waste from the old electrodes, which may amount from 10 to 30 per cent of the total consumption.

Ordinary coal or coke cannot be directly used for the manufacture of electrodes, as even the purest anthracite will give electrodes having an ash content of more than 2 per cent, of which at least 13 per cent is silica. Natural graphite or baked carbon is not sufficiently pure, and graphite is in general too expensive for aluminium production in that its high electric conductivity cannot be utilized. The current density should be from about 0.6 to 1.0 ampere per sq.cm. and even a lower density is often used. The consumption is not reduced by using graphite, because it is the oxidation during the electrolysis which consumes the electrodes. Retort graphite may be used, but this contains as a rule too much silica, so that it is used in addition to other materials. Acheson graphite is very pure, but is now too expensive in Europe. In general petroleum coke is the best material, although it is high priced. It has a low ash content of from 0.1 to 0.4 per cent and seldom goes over 0.5 per cent. The American petroleum coke is generally purer than the Rumanian. It is produced by distilling heavy crude oil which is heated to a dark red heat, the product being a porous, partly hard and partly soft shining mass with a grain-like structure.

Petroleum coke contains 10 to 15 per cent of readily volatile matter, or even as high as 20 per cent. This volatile matter must first be driven out by calcining at red heat, otherwise it is impossible to obtain good solid electrodes. The larger pieces of the coke are first crushed in ordinary crushers to the size of a walnut. The ovens, such as designed by Frans Meisser, are about

FIG. 11. VERTICAL ELECTRODE PRESS

Oresund or La Compagnie des Produits Chimiques d'Alais et de la Camargue, it contains about 50 per cent fluorine and 12 to 13 per cent alumina, but only  $\frac{1}{4}$  to  $\frac{1}{2}$  per cent silica and  $\frac{1}{10}$  per cent iron.

Cryolite melts at about 1000 deg. C., and when heated to red heat it liberates up to 1 per cent of water. At white heat sodium fluoride and fluorine will gradually escape and the alumina will be left. The artificial cryolite contains more fluorine, its chemical formula being  $\text{AlF}_3 \cdot 4\text{NaF}$ . It is, therefore a better raw material, but it smokes more. It is produced by treating hydrated alumina and ordinary salt with hydrofluoric acid or by other methods. The hydrofluoric acid must first be produced and is made by distilling a mixture of pulverized fluorspar with concentrated sulphuric acid, the HF being absorbed in water. Such a still is

5 x 6 m. and about 6 m. high with 8 retorts having an inside diameter of about  $\frac{1}{2}$  m. These retorts are filled from the top and emptied successively every three to four hours through water-cooled passages in the bottom. The retorts are heated by gas, which first passes through an economizer, which comprises one-half side of the oven. The preliminary heating takes nine to twelve hours.

After the calcining, the petroleum coke, together with the old waste electrodes, is pulverized and some retort graphite is added. If the pieces are large it may first be necessary to pass them through crushers, and thereafter pulverize them in ball mills. The petroleum coke is now mixed with up to 20 per cent of a pitch binder. Some plants use tar thickened with about one-third pitch. A little soot will make the electrodes more homogenous, but it is as a rule likely to be too impure. In order to protect the electrodes from burning it is also recommended that a little alumina be added. If the tar contains water, it should first be heated to evaporate it. Coal tar pitch obtained from coke ovens may be used, as it contains not over 1 to 2 per cent of ash, but one must be careful and not use blast furnace tar, which often contains as high as 20 per cent of ash.

The substances are mixed in steam heated kneading machines. Such a machine has two Z-shaped kneaders, which rub on each other and the steam jacketed chamber walls. When the mixture is sufficiently kneaded the container is opened and the mass brought by a conveyor to the molds or presses. In these they obtain their final form and compactness, the pressure being up to 500 atmospheres. The higher the pressure, the more compact will the electrodes be and the less binder will be required, which is an advantage, as the space occupied by the binder will always be more or less void when the electrodes are baked and the tar oils volatilized.

The construction of the presses depends naturally on the size of the electrodes. In an aluminium furnace it is advisable to use several electrodes so as to make it possible to make renewals without breaking the current or lower the potential. Several furnaces or ovens, up to 40, may be connected in series and the electrodes are constantly being changed and adjusted. If the current had to be broken at each change of electrode, a continuous operation would be impossible. The size of the electrodes depends both on the number and on the electric current which the furnaces require. From 8000 to 10,000 amperes is common, while much larger sizes are in use, requiring a current of from 15,000 to 20,000 amperes. The cross-section of the electrodes varies from 20 x 20 sq.cm. to over 40 x 40 sq.cm., and the length may be more than 1 m., although it is common practice to use a nearly cubical form for the larger sizes.

The electrode press, shown in Fig. 11, is of the vertical type and equipped with a preliminary press and a turntable. The cylinder is first packed full with the mixture by the outer piston and then moved to the middle position, where the center piston presses it through the mouthpiece. If short electrodes are desired, they are simply cut off to the required length. Such a press is about  $4\frac{1}{2}$  m. high and takes up a floor space of 4 to  $5\frac{1}{2}$  m. It can press the largest electrodes needed for the aluminium industry.

Another method is that of pressing the short electrodes directly in a mold, in which case the mass does not pass through any mouthpiece. There are many designs of vertical and horizontal electrode presses with or without preliminary presses, but as a rule the simplest and the strongest are the best.

After the electrodes have been pressed and formed they are baked in furnaces. This makes them solid, compact and highly electro-conductive due to the re-

FIGS. 12 AND 13. CROSS-SECTIONS OF MENDHEIM-JEHL ELECTRODE FURNACE

moval of the insulating tar oils. The heating must be done slowly, otherwise they may be less compact and may easily crack. Thus, for example, several days are required for firing the larger electrodes. The temperature is gradually raised to more than 1400 deg. C. and during the operation the electrodes lose about 10 per cent of their weight.

Modern European furnaces are gas fired and the electrodes are protected by being placed in crucibles of a refractory material. The empty space around them is filled with retort graphite, which is a good heat conductor, or with pulverized petroleum coke or electrode waste.

Much experimenting has been done to do away with the gas producer and to get the gas from the fresh pe-

troleum coke in the retorts. No satisfactory method was, however, found until a few years ago, as the mass shrunk so much that the electrodes became directly exposed to the flames.

Of the many different furnace designs may be mentioned Mendheim's muffle furnace of the Bock type, where the electrodes are passed through a passageway toward the center of the furnace, where the heat is greatest. The electrodes are placed on trucks, which thus are pushed through the furnace by hydraulic pistons. They are preheated by the waste gases and cooled by the air required for the furnace draft, which in this manner also becomes preheated. The electrodes are

FIG. 14. MEISSER FURNACE

baked in this furnace at a temperature of 1350 deg. C., which is sufficient for electrodes to be used in aluminium reduction where the temperature of the bath is around 1000 deg. C.

A modification of the above furnace has been devised by Jehl, and consists of a system of partitions or chambers. Figs. 12 and 13 show the center portion of such a furnace where the baking takes place. The tunnel on both sides of the furnace has a similar section; and the waste gases pass the economizer on one side and thus preheat the electrodes which are brought into the furnace. The air cools the finished electrodes and is further heated by the economizer.

The more generally used ring-furnace is that of Frans Meisser. As seen from the diagrammatic sketch in Fig. 14, it consists of sixteen chambers on each side

FIG. 15. SECTION OF MEISSER FURNACE

of a gas flue. These chambers may be 2 m. long, 1.5 m. high and 1.5 m. wide, or even larger. Two of the chambers are always idle for taking out finished electrodes and for putting in new ones and can be separated from the others by removable partitions. Fresh air enters the furnace from neighboring chambers and is heated in the next five or six chambers, while these as

well as the electrodes therein are cooled. In the next or next two chambers the producer gas is burned and gives off its heat to the following six chambers, after which the waste gas passes off through the chimney.

In the other side of the furnace the process is similar, and as the electrodes are baked and replaced by fresh ones the chambers are cut in and the neighboring one opened and emptied, and so on, according to a predetermined cycle of operation.

Fig. 15 shows the construction of the furnace, the gas flue being in the center between the two rows of chambers. By means of a double elbow pipe the gas is led down and out through the small openings, where it meets the air and burns. The air has entered in the previous chamber, where the pipe has been removed. When a chamber is to be emptied, inspected or recharged, the cover is removed by a traveling crane; the partitions which separate the chamber from the rest must, however, first be put in place.

Mendheim has recently designed a ring-furnace, where retorts are unnecessary in that the chambers

FIG. 16. TYPES OF ELECTRIC INSTALLATION

themselves serve this purpose. They are surrounded by hollow walls through which the gases pass. Fresh coke is used as the packing filler and is tamped tight around the electrodes to such a thickness over them that they will not become exposed when the coke shrinks down. The most remarkable feature of his furnace is that after the material has become ignited for a time by the aid of a small gas-producer the latter can be shut down and the distillation gases from the volatile matter in the binder of the electrodes and the coke filler can be utilized for heating the furnace itself. It is claimed that the gas supply is more than sufficient to bring the furnace temperature up to the highest values.

#### THE ELECTRIC INSTALLATION

The raw materials for aluminium production, i.e., alumina, cryolite and the electrodes, have been dealt with in the above, but in addition to these a large supply of direct current is required for electrolysis and heating the furnace. Each aluminium furnace takes from 6½ to 7½ volts, and in starting it requires wider limits, from 5½ to 8½ volts. It is, of course, not economical to build generators of such a low voltage and from 30 to 40 furnaces are, therefore, connected in series. The operating voltage for 35 furnaces in series will, therefore, be about 250 volts.

As is apparent from diagram 1 in Fig. 16, it is preferable if the aluminium works can be located near the

power house. The direct current generator can then be directly driven by the turbine and the current delivered economically to the furnaces. The regulation from zero volts up to maximum is accomplished simply

FIG. 17. VERTICAL SECTIONS OF ALUMINIUM FURNACE

by a field rheostat. If several generators are required, they may be operated in parallel. If there are several series of furnaces, these can then be operated independently of one another. This simple arrangement should be used if the waterpower is located near a port, while if it is located in the interior, it depends on the local transportation facilities whether the factory should be built near the power house or not. If not, the energy may be transmitted over a transmission line according to diagram 2 or 3. In both these cases the turbine drives a 3-phase alternating current generator, and if the distance between the factory and the power

FIG. 18. HORIZONTAL SECTION OF ALUMINIUM FURNACE

station is great, it may be necessary to step-up the voltage to a higher value by means of transformers.

In diagram 2 the conversion of the 3-phase alternating current to direct current is accomplished by a synchronous converter, and in diagram 3 by a motor-generator. The former gives a little higher efficiency, but the direct current voltage cannot be regulated from zero and up, and if adjustments are required, the trans-

FIG. 19. MELTING POINTS OF ALUMINA-CRYOLITE

former taps must be changed or a booster must be provided. This is connected in series with the alternating current supply circuit, and by increasing or decreasing its field excitation, the voltage which is applied to the converter terminals is raised or lowered, thus also raising or lowering the direct current voltage. Synchronous converters are mostly used in America and England, and motor-generators on the Continent.

As shown in Fig. 16, voltmeters and incandescent

lamps are used for reading the voltage of each furnace, and the current, which is, of course, the same for all the furnaces in the series, is measured by an ammeter and the main potential by a voltmeter. The instruments on the alternating current side are not shown.

### THE MANUFACTURE OF ALUMINIUM

The aluminium furnace in Figs. 17 and 18 has the electrodes supported by means of copper bars from a set of crossbars. The vertical bars are fastened to the crossbar by means of clamps and bolts or keys and to the electrodes by means of a bolt which is screwed or molded into the electrode. The furnace casing is lined with carbon and the current enters from the crossbar, through the furnace and down to the iron bottom which comprises the negative pole.

To start the operation the electrodes are all lowered, the current is thrown on, and as the furnace heats up it is filled with cryolite, which melts. If the bath gets

FIG. 20. ELECTRODE CONSUMPTION

too high, the electrodes can be raised by adjusting bolts. The furnace is tapped or scooped out every third or fourth day, the ingots varying in size from 2 to 40 kg.

The cryolite melts around 1000 deg. C., but if a little alumina is dissolved therein the melting temperature drops as shown in Fig. 19, the melting point being at a minimum with 5 per cent alumina dissolved. With from 8 to 9 per cent alumina a break in the curve seems to occur, and the cause of this is probably that the composition of the cryolite has been changed. If aluminium fluoride is added, the temperature will drop still further, and aluminium fluoride will also more readily dissolve the alumina. With 20 to 30 per cent alumina, the bath becomes thicker and there is danger that the alumina may only not dissolve but sink to the bottom, whereby the resistance will increase and cause local heating, or the aluminium together with the carbon may

FIG. 21. ALUMINIUM FURNACE USING CRYOLITE CRUST FOR CONTAINER

form a carbide,  $\text{Al}_4\text{C}_3$ . This aluminium carbide, which generally is formed when the operation is carried on at too high a temperature, is yellow and of hexagonal crystallization. When mixed with water at ordinary temperature, it forms slowly alumina and methane gas.

Moisan has therefore drawn the conclusion that the methane vapors which issue from the ground may be caused by aluminium carbide in the interior of the earth.

The temperature is also of importance as far as the electrode consumption is concerned, and as shown in diagram 2, Fig. 20, at an excessively high temperature the air will quickly oxidize the electrode. Not enough

FIG. 22. UNIT NEGATIVE ELECTRODE AND CONTAINER

distance between the electrodes creates a condition as shown in diagram 4. If the bath is too high, the electrodes will be pointed, as in diagram 5, and if the contacts are poor, they will take a shape as in diagram 3. Diagram 1 shows the desired form.

The temperature also affects the composition of the bath in that at high temperatures the fluorine evaporates and must be replaced by aluminium fluoride. At a low temperature, a hard crust is formed over the bath. As the aluminium melts at from 625 to 700 deg. C. it may be difficult to draw off the metal at a low temperature, or it may rise in the bath and cause a short circuit of the furnace. When aluminium approaches the solid state, it becomes lighter than the bath, while in a molten form it is slightly heavier. For these reasons it is often necessary to cut out a furnace of the series, and it happens also that a hole is burned therein or that the electrodes get stuck or "freeze," so that they cannot be regulated. One electrode may then get too much current or the copper connections may melt, and if things go wrong all the copper bars, one after the other, may melt. If it has been decided that a furnace is to be cut out, this can be done by connecting both

FIG. 23. HALL'S ORIGINAL FURNACE

and the current in the series may be reduced until the new furnace is hot enough to melt the cryolite.

The temperature has also to do with the electrode consumption, and carbon monoxide is formed at high temperatures and burns with a blue flame, which also may be yellow on account of the sodium present. At ordinary temperatures between 800 and 1000 deg. C. carbon dioxide is also formed. The proportion of the volume of the waste gases varies from 5 to 10 and even up to 20 parts of carbon monoxide for 100,000 parts of carbon dioxide. It has, however, been proved that these gases are not dangerous to the operators in the furnace room.

The formation of the carbon dioxide occurs from the electrolysis of the dissolved alumina, and if all the alumina is decomposed the electrolysis may proceed with the aluminium fluoride. The fluorine forms then with the anode carbon tetrafluoride, a gas which is dissolved in water without being decomposed. This gas is, however, harmless. In any case, the furnace operator notices immediately when the alumina is consumed, as the furnace voltage rises from the normal 7 volts up to around from 15 to 17 and even up to 20 volts. The

FIG. 24. LAMBERT'S FURNACE

incandescent lamp brightens up, the voltmeter needle swings over and the operator knows that more alumina must be added to the bath.

It has never been possible to find hydrofluoric acid in the gases from the aluminium furnaces. It was thought that hydrofluoric acid was the cause of the windows becoming dull, but when the bath or the electrodes contain some silica, the gases were found to contain about 20 per cent of silicon-tetrafluoride. This gas, due to the moisture in the air, will attack glass and make the windows dull; it also attacks copper in the neighborhood of the furnace and blackens it. The pine trees near the factory suffer also somewhat from the gases.

When a furnace gets "hot," for example over 1000 deg. C., a process takes place which is opposite to that which takes place when aluminium is produced. At higher temperatures the sodium fluoride of the bath is reduced, the sodium rises to the surface in small balls and burns with a lively yellow flame. With "hot" furnaces the aluminium will quickly dissolve the iron rakes which are used. A 900 to 950 deg. C. temperature of the bath seems to be the best, although some advocate

the terminals to the bar or by using jumper connections. In this manner it is possible to short circuit a furnace and disconnect the same without disturbing the rest of the series. A new furnace can be cut in in the same manner, the electrodes may be lowered to the bottom

a lower temperature, 800 to 900 deg. C. The furnaces will then, however, be much more difficult to operate. Each operator can take care of from four to five furnaces.

Fig. 21 shows a frequently described furnace without carbon side linings. The intention is that the cryolite bath shall get hard and insulate the iron sides, but if it does not, the result is that there will be an iron content in the aluminium and the furnace may readily be damaged.

Fig. 22 shows how the negative terminal can be molded into the bottom mass. This construction is, however, used in only a few places.

Fig. 23 illustrates Hall's furnace, which, however, is of only historical interest commercially.

Fig. 24 is Lambert's furnace, the bottom of which consists of electrodes fitted into a cast-iron frame. This construction is still in use.

#### INDUSTRIAL APPLICATIONS OF ALUMINIUM

Aluminium can readily be cast and fills the molds well. When nearing its melting temperature it gets doughlike and contracts about 1.8 per cent in volume. By shaking it between 550 and 625 deg. C., it pulverizes. It is also generally resmelted if it is to be

larger and larger furnaces having capacities of several tons.

Aluminium can be resmelted without taking up gases and without forming blowholes, but it gets covered with a thin film of oxide. Its purity should not be less than 98 per cent, and if it is to be used for rolling,

FIG. 26. CROSS-SECTIONS OF ROUSSEU'S FURNACE

where strength is essential, its purity should preferably be 99 per cent.

High-grade aluminium which does not contain more than  $\frac{1}{100}$  per cent sodium,  $\frac{1}{100}$  per cent iron and  $\frac{1}{2}$  per cent silica can be forged, rolled, drawn or punched, and can also be brazed and soldered. Aluminium may, therefore, take the place of tin foil and in certain countries aluminium money is used instead of nickel. In America aluminium is extensively used for cans for fruit and other conservation, and in Sydney they use an aluminium alloy, called Ormiston, for this purpose entirely.

Aluminium is used in the form of sheets, pipes, cables or cast parts for automobiles, aeroplanes, etc., and pipes for carrying nitrous gases. Due to its lightness (2.7 against 8.9 for copper), its conductivity (34 against 57 for copper) and its comparative strength (22 against 44 for copper), aluminium is rapidly replacing copper in the electrical industry. To get the same conductivity only one-half the weight of aluminium is required as of copper. In reality aluminium is, therefore, twice as good a conductor as copper, when the conductivity is compared to the weight. As, furthermore, this one-half the weight of aluminium occupies a greater volume than copper, it follows that the heat radiation of a transmission line must be better than a copper line. An aluminium conductor can also better withstand the stress caused by its own weight, as its low specific weight in this case is of greater importance than its lower strength.

According to the law of Faraday, the production of 1 kg. aluminium requires 2969 amperes for one hour,

FIG. 25. ROUSSEU'S FURNACE

rolled or pressed, and the Rousseu furnace is widely used for this purpose, the construction being shown in Figs. 25 and 26. The retort is of graphite and the furnace is fired with coke. Plates up to 1.10 x 1.10 x 0.12 m, weighing from 300 to 400 kg. may be cast for use in rolling large sheets and the tendency is to construct

but in actual practice 5 to 10 per cent more is required. The voltage needed for the melting of the alumina is, according to Thomson, 2.8 volts, and from this must be subtracted the potential for the formation of the carbon dioxide and carbon monoxide, and to it must be added the potential corresponding to the resistance of the furnace and which heats the bath. In practice the total voltage is figured to be between 6.5 and 8.5 volts, but if extra long electrodes are used the voltage may be still higher. One kg. of aluminium has been produced with 25 kw.-hours, but 33-35 kw.-hours per kg. may be considered a good result.

The alumina consumption is theoretically 1.888 kg. per kg. aluminium and in practice 1.95 to 2 kg. The theoretical electrode consumption is 0.666 kg. or 0.333 kg. per electrode per kg. of aluminium, depending on how much carbon monoxide or carbon dioxide is formed. If the waste is subtracted, the consumption will go below 0.666 kg., which proves that carbon oxide is formed. An electrode consumption of from 0.7 to 0.9 kg. per kg. aluminium with a salvage of 0.2 to 0.3 kg. may be considered a good result.

#### COST

In order to give an idea of the various items which enter into the cost of manufacturing aluminium, the following tabulation has been prepared. It is, of course, greatly dependent on local conditions, and refers to normal conditions before the war:

| Per Kg. Aluminium                 | Frs  |
|-----------------------------------|------|
| 55 kw. hours at 0.7 centimes..... | 0.25 |
| 2 kg. alumina at 0.25.....        | 0.50 |
| 0.8 kg. electrodes at 0.35.....   | 0.28 |
| 0.12 kg. cryolite at 0.40.....    | 0.05 |
| 0.05 kg. fluorine at 0.50.....    | 0.03 |
| 0.25 Working hours at 0.60.....   | 0.15 |
| Miscellaneous.....                | 0.15 |
| Total: Frs. ....                  | 1.41 |

#### WORLD'S PRODUCTION OF BAUXITE (TONS)

| Country              | 1913    | 1915    | 1917    |
|----------------------|---------|---------|---------|
| United States .....  | 210,241 | 297,041 | 568,690 |
| France .....         | 304,314 | .....   | .....   |
| United Kingdom ..... | 8,282   | 11,723  | 14,724  |
| Italy .....          | 6,841   | 5,807   | .....   |
| India .....          | 1,184   | 876     | .....   |
|                      | 530,862 | .....   | .....   |

By this table it will be seen that the United States is assuming a leading position in the production of bauxite.

## Industrial Reconstruction in Great Britain

ON NOV. 12 last, one day after the armistice was signed, a Parliamentary paper was issued in London announcing the appointment of an Advisory Council and other councils and committees by the Minister of Reconstruction. The Advisory Council consists of a panel of men and women of mature experience and distinction in affairs. It is divided into five sections, each of which meets once a week. Their purpose is to advise on questions of special difficulty or complexity that may come before the Ministry. An informal committee of women members of the Council will meet regularly to give advice as desired in connection with questions affecting the position of women. The five sections relate respectively to (1) Finance, Transport and Common Services, (2) Production and Commercial Organization, (3) Labor and Industrial Organization, (4) Rural Develop-

ment, including Agriculture, and (5) Social Development, including Health, Education and Housing.

Another Council was appointed which has to do with the disposal of surplus Government property.

The Engineering Trade Committee is also a creation of the Minister of Reconstruction, and its purpose is "to compile a list of the articles suitable for manufacture by those with engineering trade experience or plant which either were not made in the United Kingdom before the war but were imported or were made in small or insignificant quantities in the United Kingdom and for which there is likely to be a considerable demand after the war." These are classified as to whether they are capable of being made by women, or by men and women, or by skilled men. The committee is to set forth where such industries may be most suitably attached, to make recommendations on their establishment and development by transfer of labor and machines or otherwise, and how such transfers may be made, as well as what organization is requisite with due regard to securing the coöperation of labor.

In this connection the following branch committees have been appointed: Wire Machinery, Printing Machinery, Printers' General Machinery, Papermaking Machinery, Leather Manufacturing Machinery, Textile Machinery (one in Manchester and one in Nottingham), Machine Tools, Agricultural Machinery, Aircraft, Hollow-ware and Sheet Metal and Pressed Work (one committee), Electrical Apparatus, Scientific Instruments, Miscellaneous Machinery and a General Labor Panel.

Still another series of committees has been appointed to consider and report upon the nature and amount of the supplies and foodstuffs required by the United Kingdom between the close of the war and the restoration of normal conditions, having regard to the requirements of India, the Dominions and Crown Colonies, the probable requirements of belligerents and neutrals at the close of hostilities, the sources from which they may be obtained and whether any measure of control will need to be exercised, as well as the measure and extent of such control. These committees consist of ten bodies and will consider respectively aluminium, antimony, copper, lead, nickel, spelter, tin, ferro-alloys, asbestos and hides and skins.

A committee is appointed to inquire into the extent that building materials will be needed and to ascertain how and where they are to be procured.

A large committee of many members considers priority after the war. This is composed of employers and workmen and is already at work.

The Committee on Interim Industrial Relations proposed that in each industry which has reached a sufficient level of organization there be established a Joint Industrial Council, consisting of equal numbers of representatives of associations of employers and members of trade unions which shall be approved by the Government. A considerable number of such councils have been formed and the Minister of Reconstruction will consult them on questions affecting their respective industries. A still greater number are in process of organization. In regard to heavy chemicals a Joint Industrial Council has been set up which is represented on this special committee. It was formed at the suggestion of the Minister of Reconstruction to deal with technical and commercial questions falling outside the scope of the council.

# Graphic Method for Fortification of the Spent Acids Used in Making Nitrating Mixed Acids

BY D. LOPEZ AND A. A. SWANSON

THE USE of mixtures of sulphuric and nitric acids of definite composition, so-called "mixed acids" in the manufacturing processes, especially in the explosive industry, has steadily increased. The chemist has been called upon to make unlimited numbers of calculations in his work of revivifying the spent acid recovered from the nitration. Work of this nature becomes more or less involved; it is necessary to have available methods which permit of easy and rapid solution of acid problems and which possess a high degree of accuracy.

It is hoped that the brief theoretical development of the principles involved in the fortification of spent acids and their use graphically, as given in this paper, will arouse interest in this field particularly at this time and find favor among acid-control chemists.

In a mixed acid let:

N = lb. of  $\text{HNO}_3$  in 1000 lb. of mixed nitrating acid;

S = lb. of  $\text{H}_2\text{SO}_4$  in 1000 lb. of mixed nitrating acid;

W = lb. of  $\text{H}_2\text{O}$  in 1000 lb. of mixed nitrating acid;

$N_s$  = lb. of  $\text{HNO}_3$  in 1000 lb. of spent mixed acid;

$S_s$  = lb. of  $\text{H}_2\text{SO}_4$  in 1000 lb. of spent mixed acid;

$W_s$  = lb. of  $\text{H}_2\text{O}$  in 1000 lb. of spent mixed acid;

so that:

$N + S + W = 1000$  lb. of mixed nitrating acid;

$N_s + S_s + W_s = 1000$  lb. of spent mixed acid.

The following symbols shall be used:

$x$  = lb. of  $\text{HNO}_3$  added to revivify 1000 lb. of spent mixed acid;

$y$  = lb. of  $\text{H}_2\text{SO}_4$  added to revivify 1000 lb. spent mixed acid;

$z$  = lb. of  $\text{H}_2\text{O}$  added to revivify 1000 lb. spent mixed acid;

$X$  = lb. of  $\text{HNO}_3$  Aq. added to revivify 1000 lb. spent mixed acid;

$Y$  = lb. of  $\text{H}_2\text{SO}_4$  Aq. added to revivify 1000 lb. spent mixed acid;

$P_n$  = Per cent  $\text{HNO}_3$  in  $\text{HNO}_3$  Aq. used;

$P_s$  = Per cent  $\text{H}_2\text{SO}_4$  in  $\text{H}_2\text{SO}_4$  Aq. used;

$x = P_n X$ ;

$y = P_s Y$ ;

$F = (1000 + X + Y)$  lb. of refortified mixed acid;

$W_s$  = lb. of water in  $F$  lb. of refortified mixed acid;

$(N_s + x) + (S_s + y) + W_s + z = F$ .

This new mix will be equivalent to the required mixed acid composition when:

$$N_s \cdot x = \frac{NF}{1000}; S_s \cdot y = \frac{SF}{1000}; W_s + z = \frac{WF}{1000}$$

$$\frac{N_s}{N} \cdot x = \frac{S_s}{S} \cdot y = \frac{W_s + z}{W} \quad (1)$$

Substituting for  $x$ ,  $y$  and  $z$  in equation 1, we obtain

$$\frac{N_s}{N} \cdot \frac{P_n X}{S} = \frac{S_s}{S} \cdot \frac{P_s Y}{W} = \frac{W_s + z}{W} \quad (2)$$

The water introduced ( $z$ ) in adding the refortifying acids to 1000 lb. of spent acid may be expressed by the following equation:

$$Y(1 - P_s) + X(1 - P_n) = z = W_s - W_s \quad (3)$$

by transposition,  $P_n X = Y(1 - P_s) + X - W + W_s$ ,

and substituting for  $P_n X$  in the nitric ratio in equation 2 we have:

$$\frac{N_s + Y(1 - P_s) + X - W_s}{N} = \frac{W_s}{W}$$

transpose  $-W_s$  to the right and simplify,

$$\frac{N_s + W_s + Y(1 - P_s) + X}{N} = \frac{W_s}{W} + \frac{W_s}{N} = \frac{W_s(N + W)}{NW}$$

cancel  $N$  from the denominators and transpose  $N + W$ , to obtain the equation:

$$\frac{N_s + W_s + Y(1 - P_s) + X}{N + W} = \frac{W_s}{W} \quad (4)$$

If the term  $P_s$ , the per cent  $\text{H}_2\text{SO}_4$  in the  $\text{H}_2\text{SO}_4$  Aq. to be used in mixing, is assumed to be a constant in equations 4 and 5 obtained by referring  $\frac{W_s}{W}$  to equation 2,

$$\frac{S_s + P_s Y}{S} = \frac{W_s}{W} \quad (5)$$

it is readily seen that equation 4, on account of the presence of the variable parameter  $W_s$ , represents a system of straight lines parallel to each other. By similar reasoning it is seen that equation 5 represents another system of straight lines which are parallel to the  $X$  axis. By combining equations 4 and 5, we can eliminate the common term  $\frac{W_s}{W}$  and get an equation which is the

locus of all the points in which the systems 4 and 5 intersect. This locus is represented by the equation:

$$Y[P_s(N + S + W) - S] - SX + S_s(N + W) - S(N_s + W_s) = 0,$$

and by rearranging and substituting, with  $T$  and  $H$ ,

$$\frac{P_s(N + S + W) - S}{S} = T$$

$$\frac{S_s(N + W) - S(N_s + W_s)}{S} = H$$

the equation becomes  $TY - X + H = 0$  (6)

In equation 6,  $Y$  gives the amount of sulphuric acid of fixed strength  $P_s$ , and  $X$  the corresponding amount of nitric acid of unknown ( $P_n$ ) concentration. The determination of this develops as follows: By eliminating  $Y$  from the sulphuric ratio in equation 2 with the equivalent of  $Y$  from equation 3 we obtain:

$$\frac{S_s + P_s Y}{S} = \frac{W_s}{W} \quad (2)$$

$$Y = \frac{W_s - W_s - X(1 - P_n)}{1 - P_s} \quad (3)$$

$$\frac{W_s}{W} = \frac{S_s + P_s[W_s - W_s - X(1 - P_n)]}{S}$$

$$= \frac{S_s(1 - P_s) + P_s W_s - P_s[W_s + X(1 - P_n)]}{S(1 - P_s)}$$

$$\frac{W_s}{W}(1 - P_s)S - P_s W_s = S_s(1 - P_s) - P_s[W_s + X(1 - P_n)]$$

$$\frac{W_s}{W} = \frac{S_s(1 - P_s) - P_s[W_s + X(1 - P_n)]}{S(1 - P_s) - P_s W_s}$$

$$\frac{N_s + W_s + Y(1 - P_s) + X}{N + W} = \frac{S_s + P_s Y}{S}$$

Transposing the terms to the right member

$$NP_n Y + WP_n Y - SY(1 - P_n) - SX + S_s N + S_s W - S N_s - S W_s = 0$$

$$Y[P_n(N + S + W) - S] - SX + S_s(N + W) - S(N_s + W_s) = 0,$$

Since  $(N + S + W)$  is always equal to 1000 and  $S$  and  $P_s$  are constant;  $T$ , the tangent of the angle intercepted by the horizontal axis and the curve, must also be a constant.  $H$ , the intercept of the vertical axis, is usually positive, but the system is not altered when it is negative.

On a rectangular axis system  $XY$ , Chart I, trace a vertical line parallel to the  $y$  axis, denote this the  $P_n$  axis, and mark on it the strengths 0.98, 0.96, 0.94, etc., of the nitric acid. If parallels to the  $X$  axis are drawn through those points, intersecting parallels to the  $Y$  axis drawn through the values of  $X$ , a line drawn through the points of intersection will give the curve  $cd$ , Chart I, represented by equation 9.

Repeating the same operation with points  $X = 82.33$ ,  $Y = 110$ ,  $X = 45.57$ ,  $Y = 41.72$ , and uniting them by a straight line we obtain the curve  $ab$ , Chart I, represented by equation 8.

#### USE OF CHART I

Suppose that nitric acid of 88 per cent strength is available and that the spent and mixed acids are of strengths above mentioned, then in order to get the amounts in units of sulphuric and nitric necessary to build up the spent acid we proceed as follows:

At the point marked 88 per cent on Chart I, follow horizontally until intersecting the curve line  $cd$ , at  $m$ , from this point drop down parallels to the  $Y$  axis intersecting the straight line  $ab$ , and  $X$  the axis in  $n$  and  $p$  respectively; the first intersection  $n$  gives in the sulphuric acid scale the amount of 100 per cent sulphuric, and the second intersection gives the amount of nitric acid.

In the above instance the readings are as follows:

$X = 60.60$  units;

$Y = 69.68$  units;

Total = 130.28 units;

Spent acid used 1000.00 units;

Total mix made = 1130.28 units.

|                                           |                                                                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| 60.6 units of 88% $\text{HNO}_3$ contains | $\left\{ \begin{array}{ll} \text{HNO}_3 & 53.33 \text{ units} \\ \text{H}_2\text{O} & 7.27 \text{ units} \end{array} \right.$    |
| 1000 units of spent acid contains         | $\left\{ \begin{array}{ll} \text{HNO}_3 & 175.00 \text{ units} \\ \text{H}_2\text{O} & 160.00 \text{ units} \end{array} \right.$ |
| and the total mix contains                | $\left\{ \begin{array}{ll} \text{HNO}_3 & 228.33 \text{ units} \\ \text{H}_2\text{O} & 167.27 \text{ units} \end{array} \right.$ |

therefore the percentage strength of the resulting mix is:

$$\frac{228.33}{1130.28} = 20.201 \text{ per cent } \text{HNO}_3$$

$$\frac{167.27}{1130.28} = 14.799 \text{ per cent } \text{H}_2\text{O}$$

Should other strengths of nitric than 88 per cent be used the same outline could be followed.

#### FORTIFYING ACIDS

Observing the curve  $ab$ , Chart I, it is readily seen that each point represents a mixture of sulphuric and nitric acids of definite strength and in definite amounts. Now these mixtures, high in nitric and low in water, are called fortifying acids, and can be obtained by reading the amounts on the chart and computing its composition. This method is both tedious and long. In the work that follows, the solution of this important part of the problem has been simplified.

Suppose that the nitric to be used is taken as  $X$ , and the sulphuric as  $Y$ , therefore, if it were desired to make 1000 units of this mixture, the amount of nitric to be used is represented by the ratio

$$X_{1000} = \left( \frac{X}{X + Y} \right) 1000$$

and the sulphuric by the ratio

$$Y_{1000} = \left( \frac{Y}{X + Y} \right) 1000$$

Substituting the values of  $X$  and  $Y$  from equations 8 and 9

$$X_{1000} = \frac{\left( \frac{C}{AP_n - 1} \right) 1000}{\frac{C}{AP_n - 1} + \frac{C}{AP_n - 1} - H} = \frac{\left( \frac{C}{AP_n - 1} \right) 1000}{\frac{TC + C - H(AP_n - 1)}{T(AP_n - 1)}} = \frac{(TC)1000}{(T + 1)C - H(AP_n - 1)} \quad (10)$$

applying the same process.

$$Y_{1000} = \frac{[C - H(AP_n - 1)]}{(T + 1)C - H(AP_n - 1)} \quad (11)$$

Now on to the assumption that  $X_{1000} + Y_{1000} = 1000$ , it will only be necessary to calculate one of the expressions and deduct the others by subtracting from 1000.

In order to simplify calculations allow for  $P_n$  constant variations and compute the resulting differences for

CHART II. CHART FOR MAKING FORTIFYING ACID WITH 104 PER CENT OLEUM OR 95 PER CENT  $\text{H}_2\text{SO}_4$

$H(AP_n - 1)$  when  $P_n$  takes the values  $P_n, P_{n_1}, P_{n_2}, \dots$  as follows:

$$H(AP_{n_1} - 1) - H(AP_{n_0} - 1) = HAP_{n_1} - H - HAP_{n_0} + H = (P_{n_1} - P_{n_0})HA$$

consequently if  $V_1, V_2, \dots$  are the different values for  $H(AP_n - 1)$  we have

$$V_0 = H(AP_{n_0} - 1);$$

$$V_1 = H(AP_{n_0} - 1) + HA(P_{n_1} - P_{n_0});$$

$$V_2 = V_1 + HA(P_{n_2} - P_{n_0});$$

$$V_3 = V_2 + HA(P_{n_3} - P_{n_0});$$

$$V_n = V_{n-1} + HA(P_{n_1} - P_{n_0}).$$

The values for  $X_{1000}$  and  $Y_{1000}$  computed from equation 10 are given in the following table and have been used for plotting the curve, Chart II, for the making of fortifying acids.

| $P_n$ | $X_{1000}$ | $Y_{1000}$ |
|-------|------------|------------|
| 0.80  | 42.83      | 57.17      |
| 0.82  | 43.69      | 56.31      |
| 0.84  | 44.60      | 55.40      |
| 0.86  | 45.55      | 54.45      |
| 0.88  | 46.54      | 53.46      |
| 0.90  | 47.58      | 52.42      |
| 0.92  | 48.66      | 51.34      |
| 0.94  | 49.79      | 50.21      |
| 0.96  | 50.98      | 49.02      |
| 0.98  | 52.22      | 47.78      |

To simplify drawing of curve even figures have been assumed in some instances.

CHART III. FORTIFYING ACID CURVE

For practical purposes when  $P_n$  changes from a value of 1.00, say 0.95 to 1.05, corrections are to be made as follows:

$P_n > 1$  correction equals  $-(P_n - 100)$ ;

$P_n < 1$  correction equals  $+(100 - P_n)$ .

Usually when doping a spent acid with fortifying acid the calculations are based on the water and nitric content. It is necessary, therefore, to have an exact relation existing between those components in the fortifying acid. This phase is developed as follows:

Equation 10 gives the amount in units of nitric acid of strength to make 1000 units of fortifying mixture, therefore the 100 per cent nitric acid contained in  $X$  units will be,

$P_n X$ , or according to equation 10,

$$P_n X_{1000} = \frac{P_n TC 1000}{(T+1)C - H(AP_n - 1)} - N \quad (12)$$

and the water per cent will be,

$$W = X_{1000} - N = \frac{(TC)1000 - (P_n TC)1000}{(T+1)C - H(AP_n - 1)} \quad (13)$$

Eliminating  $P_n$  in equations 12 and 13 we obtain,

$$N = \frac{(TC)1000}{(T+1)C - H(A-1)} - \frac{[(T+1)C - H]1000}{(T+1)C - H(A-1)} \cdot W \quad (14)$$

#### DERIVATION OF CHART III

Equation 14 is the locus of all fortifying acids that, with the spent acid considered, will make the nitrating mixed acids come within the specified limits in component strengths. Its form and degree are those of a straight line, very easy to plot. Take, for instance,

two points corresponding to the values  $W = 0$  and  $W = 100$ , then  $N = 533$  and 310 respectively. These two points are sufficient for plotting the straight line, Chart III.

This O.K. fortifying acid curve can also be constructed by another method. Let  $D_N$  and  $D_W$  be the differences in amounts of the nitric acid and water between the nitrating and the spent acids. Let  $N_F$ ,  $W_F$ ,  $N$  and  $W$  be the nitric acid and the water in 1000 lb. of fortifying acid and the nitrating acid respectively. Let  $F$  equal the amount of fortifying to be used in order to obtain in  $A_s$  units of spent acid the increase  $D_N$  in nitric and the decrease  $D_W$  in the water. Therefore,

$$D_W = \frac{(W - W_F)}{A_s} F \text{ and } D_N = \frac{(N_F - N)}{A_s} F$$

$$\frac{D_N}{D_W} = \frac{N_F - N}{W - W_F}; \text{ now if to } W_F \text{ the values } 0, 1, 2, \dots$$

be given we get the corresponding values for  $N_F$ . Since this equation is that of a straight line, two points are sufficient for constructing the curve.

#### CHART FOR MAKING NITRATING MIXES

Let the amount of spent acid used for fortification equal  $A_s$ , and the amount of fortifying acid necessary equal  $F$ ,  $W_S$  = the water in the spent acid and  $W_F$  = the water in the fortifying acid and  $W$  = the water in the nitrating acid, then we have,

$$A_s W_S + F W_F = (A_s + F) W = A_s W + F W.$$

Therefore,  $A_s(W_S - W) = F(W - W_F)$ , and finally,

$$W_S - W = F \frac{(W - W_F)}{A_s} \quad (15)$$

In this equation  $W_S - W$  expresses the difference in water to be obtained by the addition of fortifying acid of definite content  $W_F$ , consequently if we assign values to  $W_F$  of 0, 1, 2, ...,  $n$  we get in each case the equation of a straight line of the Form  $Y = aX$ , all having the same origin. Now if we give to  $A_s$  the particular value 1000,  $F$  will represent in each case the amount of fortifying acid to be used for each 1000 units of spent acid for getting the reduction in water equal to  $(W_S - W)$ . If instead of the water, we consider the nitric acid, we will realize that we ought to have an increase in the percentage of nitric and then the equation would become,

$$N - N_S = \frac{(N_F - N) F}{A_s} \quad (16)$$

and this equation has the same properties as equation 15.

The construction of the chart then follows.

Take a vertical axis upon which we will count the  $F$  values, give values to  $A_s$  equal 1000,  $W_F = 0, 1, 2, 3, \dots n$  and take  $(W_S - W) = 10$  construct on the left hand side the resulting radial straight lines.

Assigning to  $N_F$  values between 250 and 500 make  $(N - N_s) = 30$ , then construct the lines on the right hand side of the axis Chart IV. The accuracy of the chart depends on the scale used.

Several instances showing the simplicity of its uses will be developed.

First—Computation of the O.K. fortifying acid nec-

essary to make a nitrating mixed acid by fortifying spent acid. Take for instance,

Water in the spent acid, . . . 16.00 per cent  
 Water in the mixed acid, . . . 14.80 per cent  
 Water to be reduced, . . . . . 1.20 per cent  
 Water in the fortifying acid, 6.00 per cent

#### Procedure:

Follow the water line marked 6 per cent until intersection of the vertical line marked 1.20 per cent. From this point go horizontally until intersection of vertical axis at a point reading 14,000 (see Chart IV). This means that for each 1000 units of spent acid we shall add 140 units of fortifying acid. Regarding the nitric content, we assume that it will adjust itself automatically within the specified limits, since the fortifying acid used is an O.K. one.

#### Second—

Spent acid  $\left\{ \begin{array}{l} \text{H}_2\text{O} = 16.40 \text{ per cent} \\ \text{available HNO}_3 = 17.30 \text{ per cent} \end{array} \right.$   
 Mixed acid to be made  $\left\{ \begin{array}{l} \text{H}_2\text{O} = 15.10, \pm 0.05 \\ \text{HNO}_3 = 20.00, \pm 0.50 \end{array} \right.$   
 Fortifying acid to be used  $\left\{ \begin{array}{l} \text{H}_2\text{O} = 5.00 \\ \text{HNO}_3 = 44.00. \end{array} \right.$

Water is to be reduced 1.30, nitric to be increased 2.70 to 3.20 per cent.

Chart IV gives on the line 5 per cent and that corresponding to the water reduced 1.30 per cent, 13,500, or 135 fortifying acid units for 1000 units of spent acid. The increasing nitric acid will be taken according to the reading on the chart, upon the same line, 135 and line 44 per cent and equals 3.20 per cent. Then the resulting mixed acid should be

$\text{H}_2\text{O} = 16.40 - 1.30 = 15.10 \text{ per cent}$   
 $\text{HNO}_3 = 17.30 + 3.20 = 20.50 \text{ per cent}$

Third—To determine the percentage composition of water and nitric in the spent acids.

Fortifying acid used in making mixed acid,

$\text{H}_2\text{O} = 4.50 \text{ per cent}$   
 $\text{HNO}_3 = 44.50 \text{ per cent}$

Mixes obtained with this fortifying analyzed as follows:

| No. of Mines | Per Cent $\text{H}_2\text{O}$ | Per Cent $\text{HNO}_3$ |
|--------------|-------------------------------|-------------------------|
| 1            | 15.15                         | 20.30                   |
| 2            | 15.20                         | 20.26                   |
| 3            | 15.18                         | 20.46                   |
| 4            | 15.12                         | 20.20                   |
| 5            | 15.22                         | 20.35                   |

CHART IV. CHART FOR MAKING MIXED ACIDS

Ratio between spent acid and fortifying acid used,

$\frac{A}{F} = \frac{12}{100}$  then Chart IV gives,

Water reduced = 1.22 per cent;  
 Nitric increased = 2.90 per cent;  
 consequently the spent acid had,  
 $\text{H}_2\text{O} = 15.17 + 1.22 = 16.39 \text{ per cent.}$

Fourth—Use of two fortifying acids of different composition, one strong in "nitric" and the other weak.

|                        |                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Strong Fortifying Acid | $\left\{ \begin{array}{l} \text{H}_2\text{O} = 7 \text{ per cent} \\ \text{HNO}_3 = 45 \text{ per cent} \end{array} \right.$ |
|                        | $\left\{ \begin{array}{l} \text{H}_2\text{O} = 5 \text{ per cent} \\ \text{HNO}_3 = 40 \text{ per cent} \end{array} \right.$ |
| Weak Fortifying Acid   |                                                                                                                              |

We want to reduce the water by 1.20 per cent and increase the nitric 2.90 per cent. Applying the chart for both separately we have:

Strong—Water reduced 1.20 per cent, nitric increase 3.83 per cent;

Weak—Water reduced 1.20 per cent, nitric increase 2.43 per cent.

Difference in "plus" =  $3.83 - 2.90 = +0.93$  per cent in the first.

Difference in "minus" =  $2.90 - 2.43 = -0.47$  per cent in the second, according with those differences we can see that by using two parts of the weak fortifying acid we can balance the surplus in nitric made by using one part of the strong, or in other words, we can reduce the water 0.40 per cent by using 5250 pounds of the fortifying acid with 7 per cent water (see Chart IV) and 0.80 per cent by using 8250 pounds of the fortifying acid with 5 per cent water.

Some of the mixes made up in the mixing house require small corrections to bring them within the fixed limits of nitric acid and water content respectively. These corrections can also be computed with the aid of Chart IV.

Let the fortifying acid in use be  $W_F$  per cent  $\text{H}_2\text{O}$ . Take on the central scale Chart IV the point marked 10,000; the intersections along this 10,000 line with the water straight lines will give in each case the effect obtained by the addition of that amount of fortifying acid in 100,000 units of spent acid; now if in each case we place the decimal one place to the left we will get the effect of a thousand units in 100,000 units of mixed acid. Take, for instance, water = 5 per cent and read on the intersection of this line with the 10,000 line the reading is 0.96. Make the decimal one place to the left and we get the correction .096 per cent. The correction computed by other methods for mixer containing 14.50 per cent to 15.50 per cent water is between 0.094 and 0.10 of 1 per cent. Several arrangements can be used for definite amounts of mixed acid other than 100,000 pounds. We will take two instances. First, horizontal tanks containing 150,000 pounds mixed acid, and, second, vertical tanks containing 300,000 pounds. In the first case the effect obtained with the addition of 1000 pounds of fortifying acid on 100,000 pounds mixed is in the ratio of  $\frac{100}{150} = 0.67$ ; consequently if we mark the line corresponding to 6700 pounds on the chart we will obtain the corrections by direct reading without further calculation. In the second case there is always a definite ratio between the "dip" in inches and the content in pounds, so, assuming that one inch represents 2300 pounds mixed acid, we can compute the effect of one inch fortifying acid as follows:

Correction obtained by 1000 pounds fortifying acid on 100,000 pounds mixed = C.

Correction obtained by 2300 lb. fortifying and in 300,000 is equal to 0.77 C, development as follows: correction obtained by adding 1000 lb. to 100,000 lb. = C.

The effect produced by the same addition to 300,000 lb. is equal to  $\frac{C}{3}$  and, therefore when the addition is

2300 lb. the correction becomes  $\frac{2.3 \times C}{3} = 0.77C$ .

Consequently you draw a line on the line 7.700 pounds and read, placing decimal one point to the left and get the corrections without any further calculations.

Nitro, West Virginia.

## Safe Load on I-Beam by Rule of Thumb

BY JOHN S. CARPENTER

WHEN installing new machinery or taking out old, it is often desirable to use a block and tackle. Such rigging must be attached to beams, which usually may be found around power plants and may be arranged so that they are directly over the load. In a case of this kind it is desirable to know just what safe load may be put on the beam. A rule of thumb that will give this information is as follows:

Multiply the weight per foot of the I-beam by the depth in inches and divide the product by the span in feet. The result is the safe load in thousands of pounds for a uniformly distributed load. For a single load in the center of the span, take half the foregoing result.

To the writer, who has always figured beams by the usual bending-moment formulae, this rule did not sound right. It seemed too good to be true. So he determined to prove it to his own satisfaction. Let

- $W$  = Safe uniform load in pounds;
- $L$  = Span in feet;
- $S$  = Section modulus;
- $s$  = Safe stress, 16,000 lb. per sq.in.;
- $w$  = Weight of beam per foot;
- $d$  = Depth of beam in inches.

According to the rule, then,  $W = \frac{1000wd}{L}$ . But

for a beam uniformly loaded, the safe load is  $W = \frac{8Ss}{12L}$ .

Therefore, it follows that  $\frac{8Ss}{12L} = \frac{1000wd}{L}$  or  $8Ss = 12,000wd$ , from which, letting  $s = 16,000$ , it is found that  $S = 0.1067wd$ . In other words, the section modulus is equal to the product of the weight of the beam per foot, the depth in inches and a constant 0.1067. That this is approximately true may be ascertained by comparison with any steel manufacturer's catalog.

There were cases in which the writer did not know the weight per foot of the beam in question and so could not apply the rule. So he made up a table, as follows:

| Depth of Beam, in. | Value of Constant | Depth of Beam, in. | Value of Constant |
|--------------------|-------------------|--------------------|-------------------|
| 3                  | 16,500            | 10                 | 256,000           |
| 4                  | 30,000            | 12                 | 375,000           |
| 5                  | 43,750            | 15                 | 630,000           |
| 6                  | 73,500            | 18                 | 990,000           |
| 7                  | 105,000           | 20                 | 1,300,000         |
| 8                  | 144,000           | 24                 | 1,920,000         |
| 9                  | 189,000           |                    |                   |

To use the table in applying the rule, divide the constant opposite the depth of beam by twice the span in feet. The result is the safe load hung in the center of the span. For channels the safe load is half that for an I-beam of the same size. The safe loads found by the foregoing constants will differ by only 5 or 6 per cent. from the actual safe loads.—Power, Sept. 24.

# Collective and Preferential Flotation

A Description Having Special Reference to the Bradford Process—Factors Involved in Flotation Processes—Preferential Wetting of Sulphides by Sulphur Dioxide—Use of Mechanical Beaters—Laboratory Control of Process

By GUY C. RIDDELL

Consulting Engineer, United States Tariff Commission, Washington, D. C.

**F**LOTATION is at the moment a much discussed branch of metallurgy. Indiscriminate or collective flotation, viz., the concentration of sulphides irrespective of kind into one mixed product, is generally employed the world over. Preferential flotation, viz., the separation of one class of sulphides from another into independent products, has attracted much attention of late, but is not yet generally applied in practice. This selective flotation is widely used in Australia, but there are a few instances only in which differential flotation is practiced successfully in the United States.

Though the principle of flotation dates back a number of years, it was not until sixteen years ago (1902) that active steps were taken in Broken Hill, Australia, to make practical use of the flotation property naturally possessed by mineral sulphides. Once demonstrated as a practical concentrating method, however, mine managers were quick to grasp the advantages offered by this method of treatment, and as a result various processes for the recovery of sulphides by flotation were speedily developed and used. It is curious to note that despite the great advantages of flotation, even the best of these processes are in some places still looked upon as a necessary evil. One frequently hears it referred to as a very simple but elusive method of treatment. This is undoubtedly due in many instances to a lack of appreciation of the value of testing and laboratory control.

Flotation calls for rather more special experience and skill in practical operation than do most metallurgical processes. Certain conditions peculiar to and varying with each particular ore have to be more or less rigidly maintained in the application of every form of the process. While it is true that most good metallurgy starts in the laboratory, in flotation particularly it is an axiom that the most suitable operating conditions should first be worked out in the research laboratory and subsequently passed on to the operating department. Many mistakes are made that result in the loss of values in wholesale fashion by making alterations in the running plant without knowing in advance the effect of such alterations.

## THE FACTORS INVOLVED IN FLOTATION PROCESSES

Generally speaking, there exists a more or less critical balance between the various essentials in all flotation processes. The nature and degree of crushing, the proportion of coarse and fine in the crushed ore, the density of the pulp, temperature and quantity of acid additions, the degree of agitation and (or) aeration, the kind and quality of oil or emulsifying agent used and the rate of settling of the pulp are the principal factors which require careful study. A

complete series of laboratory tests should be made to ascertain the effect of varying one or more of these factors in the case of each independent ore. Unless the sulphides are very easily floatable slight changes in the balance of any of the above conditions will often upset recoveries substantially. Fortunately the margin of latitude in the critical variables is sufficiently great in the case of most ores to leave the treatment thoroughly practical. At the same time the conditions cannot be too freely tampered with if good results are to be maintained.

It has been in a large measure due to this special requirement on the part of flotation processes that they are not applied except where ordinary gravity concentration fails to accomplish results. It also explains why flotation is looked upon with suspicion by the mill man. One finds very few instances where flotation is employed, as it should be, to replace inefficient work done by gravity methods of concentration. In other words, flotation is often tacked on only as an appendage to gravity concentration. This fact explains why some plants are only at the flotation introduction stage today, when they ought to have been reaping a rich harvest a decade ago.

## WETTED AND NON-WETTED SULPHIDES

Just as collective flotation methods have been in the past arrested in their development, so also are preferential flotation methods now running the gantlet. And since these latter methods demand a still more careful control as compared with collective flotation, one may suppose that they will take longer to come into their own. And yet it is possible that this may not be so, by reason of the fact that there exist many deposits of complex ores which are not amenable to the ordinary methods of treatment. These "diseased" ores have so far remained a locked up potential asset; with the advent of successful preferential methods of treatment they will be resolved into valuable products.

Any preferential process destined to full success must have as its basis some positive means of wetting one or more of the mineral sulphide particles, while leaving another temporarily immune to wetting. After such a treatment the non-wetted class of sulphides can then be floated by themselves, leaving the wetted sulphides submerged. Moreover, it is necessary in such a process that the wetting of the particular sulphide must be of such a nature that its air film can be restored when required, so that after the complete removal of the non-wetted class of sulphides the wetted sulphide can subsequently also be floated from the gangue.

Leslie Bradford, one of Australia's leading metal-

lurgists, has discovered such a positive direct preferential method of flotation, in the  $\text{SO}_2$  process patented by him in Australia four years ago, which has been in practical operation for the past three years in Broken Hill. The process is a very simple one and it seems destined to come into prominence, as it offers a means for the separation of lead, copper and pyrite, together with the silver and gold, from the blende—the solution of a vexing problem at many a refractory ore deposit.

#### PULP ACIDIFIED WITH SULPHUR DIOXIDE

The preferential effect in this operation is obtained by the addition to the pulp of either hyposulphite of soda and sulphuric acid, or sulphur dioxide gas. The  $\text{SO}_2$  gas is produced from burning sulphur and is allowed to bubble into a small storage box at the head of the plant. In some cases  $\text{SO}_2$  gas produced from roasting operations answers. In addition to adding the sulphur dioxide at this head box it is sometimes necessary to provide pipes for the admission of the gas into the agitators connected with the flotation vessel. It is found that under these conditions the galena and pyrite float by themselves and that the blende is wetted and refuses to float.

This preferential action is explained as follows: It can be said briefly that all flotation of sulphide ores is dependent on the presence about the particle of a gaseous envelope. Mr. Bradford solved the problem of removing the gaseous envelope from some sulphides without removing it from others. Theory suggested and experience proved that such a result could be accomplished by the action of a suitable reducing agent contained in

The fact that the blende particles are not changed chemically is of great practical importance, since those particles are not rendered permanently incapable of flotation, but only temporarily immune thereto. So long as they lie in this reducing solution they will remain wetted, but as soon as transferred from that solution and aerated (or the solution oxidized and aerated) they immediately regain their gaseous envelope and exhibit the same flotation phenomena as at first.

Having removed the galena completely, the blende is floated by itself from the gangue by either dissipating the small quantity of  $\text{SO}_2$  gas by steam or by transferring the delead pulp to a separate set of flotation boxes after the removal of the bulk of the sulphurous liquor, which is returned to the deleading section. These methods are equally successful.

The Junction North Silver Mining Co., Broken Hill, employs the former method. This company introduced the  $\text{SO}_2$  preferential process some three years ago and is quite satisfied with results. It has been in continuous operation at this mine since its introduction. It is here being used in a minerals separation impeller type of apparatus, the emulsifying agent being eucalyptus oil. About 2500 tons weekly are going through this plant.

The accompanying flow sheet shows the slimes plant in which the process is being used at the Broken Hill Proprietary Co.'s mine in Australia. This is self-explanatory. A notable feature is that no oil or other organic emulsifying agent whatsoever is employed in this plant. For some time sodium sulphate or nitre cake (from five to seven lb. per ton of slime) was added to promote emulsification of the pulp, but this is found

FLOW SHEET OF SLIME PLANT

the floating medium, this agent being one which removes the gaseous envelope without chemically changing the ore. Tests and experiments proved that sulphur dioxide gas dissolved in the liquid reduces and removes the gaseous envelope from the blende particles, without affecting the film which surrounds the pyrite or galena particles; wherefore the subsequent flotation treatment (which may conveniently be, and preferably is, performed simultaneously in the same liquid) removes the pyrite and galena (the non-wetted particles), while the sulphide of zinc (which is wetted, owing to the solution and removal of its protecting gaseous envelope) falls to the bottom along with the gangue.

not to be necessary and is no longer used. No hyposulphite of soda is now added to the pulp, sulphur dioxide gas alone being employed. The quantity of  $\text{SO}_2$  used is equivalent to  $1\frac{1}{2}$  lb. sulphur per ton slimes treated. Excellent results are being obtained from this plant, which is handling some 3000 tons per week.

#### THE USE OF MECHANICAL BEATERS

Broken Hill flotation practice in general has a distinct leaning toward the more intensive agitation methods and apparatus. There was a period at Broken Hill when it was thought that mechanical aëration (beating of air into pulp by churning) was not a necessity, but all

companies have eventually gone over to mechanical agitation of a very positive order. At the B. H. P. mill, in fact, an enclosed centrifugal pump agitator is in use—patented by Leslie Bradford in 1911—which agitates and churns the pulp under pressure. The resulting aëration and gasification is intensive and thorough, and the subsequent separation of metallic sulphides in the spitzkasten into which the centrifugal pump delivers is accomplished entirely without the use of oil in the flotation medium.

Now that  $\text{SO}_2$  preferential flotation has passed through the experimental stages and definitely taken its place among the approved processes, further extension of its application is at hand. Up to the present time the treatment has been limited to slimes, but since it effects a preferential flotation in acidulated solutions and is not upset by additions of varying quantities of oils or other frothing agents, it follows that coarse sand of floatable size can be as efficiently treated as the slimes. This is an important feature, and one that is destined to increase the scope of flotation considerably.

#### FLOTATION SHOULD NOT BE A MERE GRAVITY PROCESS FINISHER

Heretofore the treatment adopted generally in Australia has been to subject the slimes resulting from gravity concentration to preferential flotation methods in a separate flotation unit. The Broken Hill ores at center of lode carry a heavy rhodonite content, and the blende is not readily separable by gravity methods. Crude ores run 15 to 16 per cent Pb, 13 to 16 per cent Zn and 12 to 13 oz. Ag. The pulp is de-leaded to the ultimate degree by gravity methods and the de-leaded material then floated for the recovery of the blende from the gangue. I will not say that this practice is a poor one, but it is, in the opinion of some of the Broken Hill metallurgists themselves, open to criticism for the following reasons: (1) It necessitates a costly plant installation; (2) de-leading of fine grit is only partial; (3) flotation concentrates are low in grade for this reason and have to be tabled; (4) stratification of float concentrates yields indifferent results; (5) grade of zinc concentrates obtained after all these successive treatments is low; (6) recoveries of both lead and zinc are considerably lower than those obtained by preferential flotation; (7) flotation of sand and slimes in two separate flotation units requires additional plant, and recoveries are not as good as when admixed; (8) handling of slime products by themselves is expensive.

The rational treatment would be to stop concentration by gravity methods on all material as soon as it has been crushed down and reduced to floatable size, and to send the whole of the mill flow from this point direct to the preferential flotation plant. The presence of the slimes would assist the flotation of the coarser mineral, and the sand would assist the rate of settling of the slimes. The concentrates resulting from preferential flotation would call for no special means of handling. Recoveries obtained by this method of treatment would be much better, and costs would be lower. The grade of both lead and zinc concentrates would be considerably enhanced.

In fact, if an ore has to be crushed down to floatable size before concentration becomes possible, there is no reason why gravity concentration in such a case should

not be entirely dispensed with to advantage. Experiments and tests made by the Bradford process on crude ores have yielded excellent results. Mill flows after the coarse Wilfley tables, i.e. both sand and slime together, have also been tested and have been found in all cases to yield excellent recoveries and high-grade products.

The  $\text{SO}_2$  process differs from other preferential processes in that it offers a positive means of wetting the blende. It is much more elastic than other preferential processes, and, unlike these, which are only applicable to the treatment of slimes or impalpably fine mill products, it can successfully float comparatively coarse galena particles.

Experimental tests have been made on several hundred tons of pyrite-galena-zinc ores outside the Australian field, representing the complex ores of Tasmania, India, Canada, Mexico and the United States, and in every instance the  $\text{SO}_2$  treatment in the hands of an operator experienced in the process has effected an excellent separation of the lead, copper and pyrite from the blende. The ores on which the process has been tested are notably those belonging to that class of intimately mixed and difficultly separable ores known as "diseased." The complex sulphide ores of the Rosebery-Hercules mines in Tasmania containing blende, galena and pyrite gave a zinc concentrate containing up to 58 per cent Zn, with recoveries from 80 to 85 per cent.

#### THE FEATURES OF A PROPER LABORATORY CONTROL

The laboratory testing of ores by the  $\text{SO}_2$  treatment requires a considerable amount of skill and patience until the proper regulation of sulphur dioxide, temperature, sulphuric acid, density of pulp, degree of agitation, rate of settling, etc., is attained. Several instances are recorded where preliminary and even repeated tests in the hands of operators who were skilled in general flotation methods but inexperienced in the  $\text{SO}_2$  treatment were of indifferent success, these same ores yielding splendid results, however, when handled by  $\text{SO}_2$  men. It has been fully demonstrated in the several mills using the process at Broken Hill that no special skill is required in the large size plant to keep  $\text{SO}_2$  additions adjusted to suit conditions. The bulk concentrates, both zinc and lead, being turned out at Broken Hill remove any doubt that these remarks on the laboratory testing of the process might convey as to its being too neat to be practical.

There are certain points that receive careful attention at Broken Hill, as follows:

1. Density of pulp on lead section. This should not exceed 27 per cent solid by weight. Higher pulps do not yield maximum grade of lead concentrate, and the zinc concentrate in turn suffers.

2. Temperature of pulp at head of lead section. This is kept below 90 deg. F. At temperatures above this the zinc shows tendency to float.

3. Acidity of pulp on lead section. This is not allowed to go much above 0.03 per cent. Higher acidity than this acts much as does too much temperature. If the solution, however, becomes neutral, lead concentrate falls off in grade because of gangue passing over with it. Both temperature and acidity are readily controlled in practice, and results are uniform and regular.

4.  $\text{SO}_2$  pipes must not become choked. The lead con-

centrates remain clean only as long as the  $\text{SO}_2$  feed is properly delivered, and a choked pipe promptly shows itself in the color of the lead flowing from the spitzkasten. The cause of this trouble is volatilized sulphur due to excessive heat in the sulphur-burners which supply the  $\text{SO}_2$ . It is checked by having a few holes in the 3-inch  $\text{SO}_2$  main which can be opened when the temperature of the burner rises unduly, the air entering through these checking the draft and combustion at the burner.

$\text{SO}_2$  selective flotation on Broken Hill ore is producing and maintaining a notably high grade of zinc concentrates (viz., 50 per cent), with lead concentrates averaging 63 per cent. It is the only preferential process so far made known which operates in the presence of acid. This is a great advantage in that coarser size lead particles can be recovered by preferential flotation without trouble.

The Bradford process is now being worked on three companies at Broken Hill, the aggregate tonnage being put through amounting to approximately 8000 tons weekly. Its extensive adoption in Australia has come about after a number of years of more or less successful trials with various other preferential treatments that have had a vogue at Broken Hill but which have lacked the positive dependable action of the  $\text{SO}_2$  method.

## Application of Zinc in the Building Trades

BY J. A. SINGMASTER

A GREAT many persons associate the word "zinc" with a cast rod commonly used in electrical batteries. This product is brittle and crystalline and can be readily broken. They do not know that zinc is rolled and that in this shape it is remarkably ductile and tough. It is extremely resistant to atmospheric corrosion and in view of these qualities has found a tremendous application in the building trades in Europe. It displaces the more expensive metals, such as copper and lead, for roofing, flashing, spouting and guttering, with no sacrifice of durability and at considerable saving in first cost. Tin and terne-plate and galvanized iron, which we so commonly use for exterior work, are usually cheaper in first cost, but when length of life, cost of painting and replacement are taken into account they are more expensive for permanent construction.

Rolled zinc is now largely used in this country in the manufacture of so-called "leaded" glass, where rolled zinc sections of any desired shape support the glass. This zinc often is given the lead finish desired for architectural effect, and is much stiffer and more durable than the metal it has replaced. It is also made in the shape of shingles or tile, which can be treated to give most artistic effects, possessing the great advantage of permanence and unbreakability. Spouting and guttering of zinc have artistic possibilities, and in addition the owner will not be able to poke his finger through the leaders on his house at the end of three or four years, nor will he have to paint them continually.

Rolled zinc is also used largely in this country for weather-strips where permanency and ultimate cost are a consideration. It has, of course, been used for years

in fastening glass in wooden frames in the shape of the familiar glaziers' "points."

The use of zinc demands a certain familiarity with the metal, which can be had with a little practice, and the selection of the proper quality of material for any given application. Zinc can be hard, medium hard and soft rolled. Hard rolled zinc would not stand bending for seam work, while soft metal can be drawn, bent and spun into the greatest variety of shapes. One of the great drawbacks to its use in the past has been the lack of appreciation of this point. No one using brass sheet would think of ordering it without specifying the kind of brass, yet ordinary zinc sheet is expected, when bought from a dealer, to meet any and every use, without due consideration of its physical properties.

A popular misapprehension exists regarding the soldering of zinc, numerous statements having appeared regarding the solution of this supposedly difficult problem. On the contrary, zinc is one of the easiest soldered metals. Any one desiring to inspect a soldered joint can do so by removing the paper or cardboard cover from an ordinary dry battery cell, such as is used for operating doorbells, all dry battery cells being contained in soldered zinc cans.

A large expansion in the use of zinc in the building trades is certain to come here as it has come in Europe. Those who first take advantage of this development and familiarize themselves with the possibilities and uses of zinc will reap the benefits which have repeatedly come to those in every branch of industry who have studied and applied foreign improvements to American practice.

New Jersey Zinc Co.,  
New York, N. Y.

**Detinning Scrap.**—O. K. ZWINGENBERGER of Tompkinsville, N. Y., notes that in the process of detinning scrap small traces of water left on the metal or in the chlorine gas are very detrimental to the yield of tin tetrachloride. It is very difficult to remove the last traces of moisture in the reacting substances. Its presence causes the formation of crystalline tin tetrachloride which covers the metal like snow, absorbs liquid  $\text{SnCl}_4$ , and prevents the effective penetration of chlorine gas to unaffected surfaces. Thus it reduces the recovery of tin, and at the same time wastes chlorine, especially as water vapor induces the formation of iron chlorides. The inventor absorbs these traces of water by adding 5 per cent of the quantitative amount of sulphur dioxide according to the following reaction:

As  $\text{H}_2\text{SO}_4$  of greater concentration than 66 deg. B. does not dissolve iron and dry  $\text{HCl}$  is also inactive, the formation of stannic chloride is not hindered. The sulphur dioxide and the chlorine are mixed in a mixing chamber or tower at such a rate that the above reaction shall be completed some time before the recovery of the tin is completed. The rate of  $\text{SO}_2$  admission is also greater at first in order to take care of the water contained in the dried scrap. The reaction takes place in the detinning pot to a large degree and does not interfere with the formation of tin chloride, in fact by the removal of water vapor it prevents the retention of crystalline tin compounds in the treated mass. (1,260,119; Mar. 19, 1918.)

## Fusibility of Coal Ash From West Virginia Coals\*

The Method of Preparing Ash for Fusion Tests and Determining Initial Softening Temperature and Interval of Fusion—A Summary of Tests on West Virginia Coals, Including the Monongahela, Conemaugh, Allegheny and Pottsville Series

By WALTER A. SELVIG

INFORMATION concerning the fusibility of coal ash has become of considerable interest to the consumer of coal during the last few years, principally in connection with the troublesome formation of clinker which results from the melting of the ash constituents of the coal when subjected to heat.

The growing interest for such data has led the Bureau of Mines to make a general survey of the "fusing" or "softening" temperatures of the ash from well known American coals. It is hoped that this information when used together with the large number of coal analyses made available by the publications of the Bureau of Mines<sup>1</sup> will be of help to the consumer of coal in comparing the different coals and in the selection of the coal best adapted for his purpose.

This paper gives the results obtained for West Virginia coals, among which are found some of the purest fuels of the country.

The method employed for the fusibility tests was the standard gas furnace method<sup>2</sup> of the bureau. In order better to interpret the results given in the table of fusibility this method is briefly summarized here.

### PREPARATION OF CONES

The coal samples are ground to 60 mesh, with crusher, rolls and ball mill. This 60-mesh material is then placed in shallow fire-clay roasting dishes and completely ashed in a muffle furnace at a temperature of 800 deg. C. to 900 deg. C.

The resulting ash is ground in an agate mortar to pass a 200-mesh sieve. To make sure that the coal has been completely ashed, the ash after grinding is placed in fused silica capsules and ignited at 800 deg. C. for two hours, a current of oxygen gas passing through the furnace during the ignition period. This ignition is made to insure complete and uniform oxidation of the ash.

A portion of the ash is transferred to an agate mortar, moistened with a 10 per cent dextrin solution and worked into a plastic mass with a spatula. The ash is then molded into solid triangular pyramids  $\frac{3}{4}$  inch high and  $\frac{1}{4}$  inch wide at the side of the base. These cones are removed from the brass cone mold, dried and mounted in a vertical position in a refractory

base made up of a mixture of two parts of kaolin to one part of calcined alumina. Usually five cones are mounted in the same base. The base with the cones is dried carefully over the hot plate until all water is driven off, then the dextrin is burned out of the cones by igniting the mounted cones in a muffle furnace at a dull red heat, after which the cones are ready for use.

### DESCRIPTION AND OPERATION OF FURNACE

The furnace used was the No. 3 melter's furnace (Fig. 1) of the American Gas Furnace Co., natural gas and air pressure of from 2 to 3 pounds to the square inch being used. The cones, supported by a suitable mounting, are placed within a covered fire-clay crucible in the furnace. A 2-in. hole is drilled through the furnace jacket and fire-clay crucible for observation purposes, a fused silica tube carrying a thin glass window being placed in the observation hole. At right angles to the observation hole a 4-in. hole is drilled through the furnace and crucible. Through this hole a platinum-rhodium thermo-couple, protected by a glazed porcelain tube, is inserted. By proper adjustment of the gas and air a reducing atmosphere is maintained within the furnace this being accomplished by using the minimum amount of air necessary to attain the desired temperature. Under these conditions, the iron in the ash is

FIG. 1. NO. 3 MELTER'S FURNACE AND ACCESSORIES

reduced to the ferrous state, which condition gives the lowest melting points and therefore gives the lowest temperature at which clinkering may result. The temperature is gradually increased to 800 deg. C., when the rate is slowed down to not less than 5 deg. C. nor more

4. For detailed description of this method and discussion of the influence of various factors on the fusibility of coal ash, see Fieldner, A. C., and others: Field, A. L.: The fusibility of coal ash: Bull. 129, Bureau of Mines, 1918, 146 pp. (In press.)

than 10 deg. C. per minute, this rate being maintained until the end of the test, when a maximum temperature of 1500 deg. C., or 2732 deg. F., is attained.

In some instances with coal ash of an especially refractory nature the cones which did not fuse at the highest temperature attained in the gas furnace, were further heated in a molybdenum wire resistance furnace<sup>1</sup> in an atmosphere of hydrogen gas. Under these conditions temperatures as high as 3010 deg. F. and in some instances slightly higher were attained. However, a coal whose ash fuses above 2730 deg. F. should give very little trouble due to clinker formation.

The temperature readings taken were:

(1) *The initial deformation temperature.* The temperature at which the first rounding or bending of the apex of the cone takes place as shown in cone 1 of Fig. 2.

(2) *The softening temperature.* The temperature at which the cone has fused down to a spherical lump as shown in cones 2 and 3 of Fig. 2.

Only the average softening temperature is reported, together with the softening interval, which is the difference in degrees between the softening temperature and the initial deformation temperature.

#### INTERPRETATION OF FUSIBILITY TABLE

According to the West Virginia Geological Survey there are 102 known coal beds in West Virginia, of which 52 are minable. The table contains samples representing nearly one-half of these minable beds, the beds listed being among the most important in the state.

The various beds are arranged according to their geological succession, from information supplied by courtesy of the West Virginia Geological Survey together with information taken from the *Keystone Coal Catalog*,<sup>2</sup> the uppermost coal beds being listed first. The succession of coal beds, with the average softening temperatures, softening interval, ash per cent and sulphur content, is as follows:

|                                                            | Average<br>Softening-<br>Temper-<br>ature,<br>Deg. | Soft-<br>ening<br>Inter-<br>val,<br>Deg. | Ash,<br>Per<br>Cent. | Sulphur,<br>Per<br>Cent. |

It will be noted that the uppermost series given is the Monongahela series, there being no samples represent-

ing the overlying Dunkard series, which top out the highest beds in the Appalachian field; however, these coals are of very little commercial importance at the present time.

The results for each mine show the lowest softening temperature, the highest softening temperature and the average for the mine. The softening interval is tabulated in the same manner. In addition to these values the per cent ash and sulphur, on the dry coal basis, is given.

#### DISCUSSION OF RESULTS

The average values given for each bed provide a means of comparison of the different coals; however, of course, the average values are averages of the mines which are listed under each bed, consequently the

FIG. 2. TYPICAL FORMS OF CONES FUSED IN THE NO. 3 MELTER'S FURNACE

greater the number of mines sampled the more representative the values are of the bed. In some instances only a few mines are listed under the bed. In these cases the average values given are only representative of the mines sampled, and do not constitute a fair average of the bed. Beds such as the Pittsburgh, Sewell, Beckley and Pocahontas No. 3, from which a large number of samples have been tested and the softening temperature values for the various mines are uniform, the average values given may be taken as representative of the bed.

It will be noted that the softening interval values given in the table vary to a considerable extent. These values, as already explained, give the number of degrees interval between the temperature at which the tip of the cone fuses or bends and the temperature at which the cone has fused down to a spherical lump, which temperature is recorded as the softening temperature. The point at which the tip first fuses or bends is rather difficult to obtain exactly on account of the phenomena of warping and shrinking of the cones which sometimes result when the cones are subjected to heat. The softening interval is interesting mainly as a study of the viscosity of the melting ash. The softening temperature values given are the values which are used in comparing the different coals. This is the most definite and easiest point to check in the tests.

#### DISCUSSION OF COAL BEDS TESTED

Under the Monongahela series the Sewickley, Redstone and Pittsburgh beds are listed. Not sufficient mines are represented to give representative average values for the Sewickley and Redstone beds. The Pittsburgh bed, which is the most important coal bed in the

<sup>1</sup>Fieldner, A. C. and Feild, A. L., "A New Method and Furnace for the Determination of the Softening Temperature of Coal Ash Under Fuel-Bed Conditions," *Journal of Industrial and Engineering Chemistry*, Vol. 7, No. 10, 1915, pp. 829-857.  
<sup>2</sup>The Coal Catalog, Combined with Coal Field Directory, for the year 1918, Keystone Consolidated Publishing Co., Pittsburgh, Pa., pp. 579-588.

northern part of West Virginia and contains one of the most valuable fuels of the country, is fairly well represented. This bed varies considerably as to sulphur content in different regions. It will be noted, however, that the softening temperatures as given are fairly uniform, but are lower than many of the other beds listed.

The mines listed under the Conemaugh series are all coal banks from the Mahoning bed, which is of no commercial value but is mined for local use. The average softening temperature from these coal banks is practically the same as that of the Pittsburgh bed.

In the Allegheny series the lower Kittanning or No. 5 Block bed is a very important coal. This bed varies from a high volatile coal in the southwestern half of the state through an ordinary bituminous type of coal in Randolph and Barbour counties to a semi-bituminous coal in the North Potomac basin.\* As might be expected from a coal varying so much in composition, the values given for this bed vary over a wide range, but no doubt the mines listed give representative values for their immediate districts.

The coals listed under the Kanawha group of the Pottsville series are coals giving ash having a uniformly high fusing temperature. The No. 2 Gas is the most important and valuable bed of this group and is widely known commercially. This bed as well as others of this group contains coals giving ash having a high fusing temperature.

The New River group of the Pottsville series contains some of the best known coals of the country, coals having a low ash and sulphur content, also giving an ash with a high fusing temperature.

The Sewell bed, which is the most important of the New River group, is very well represented in the table. The mines tested give a very uniform fusibility of ash value, and the average value for the bed is good. This coal, which is semi-bituminous in character, is one of the famous steam-producing coals of the country and is the most extensively developed of the New River coals.

The Beckley bed, which is a very important member of the semi-bituminous coals of the New River group, shows some remarkably high fusibility values. The ash from this coal is of a specially refractory nature and this bed gives fusibility values higher than any other of the beds of West Virginia that were tested. This coal should prove of interest to consumers demanding a high grade coal giving an ash of an exceptionally high fusibility.

The last group listed and the oldest and lowermost of the West Virginia coals is the Pocahontas group, which contains the famous Pocahontas No. 3 bed of Mercer and McDowell counties. This seam produces the well known Pocahontas semi-bituminous coal, which is one of the purest coals of the country and is being used extensively as a steaming and coking coal. The average values given for this bed represent 246 samples, so should be very representative of this celebrated coal. As is seen, the figures representing the different mines are very uniform. Although the average softening temperature of this bed is not as high as some of the others, especially the Beckley bed, it is uniformly high and little trouble should be experienced from clinkering.

Grateful acknowledgment is made to A. C. Fieldner, chemist, formerly of the Pittsburgh Station of the Bureau of Mines, under whose supervision most of the tests were made. Many of the tests were made by Messrs. A. E. Hall, V. C. Allison, C. R. Locke, C. S. Purcell, W. C. Ratliff and O. C. Brown, all of the chemical laboratory of the Bureau of Mines.

Chemical Laboratory, U. S. Bureau of Mines,  
Pittsburgh, Pa.

## The War and the Nitrogen Industry\*

BY W. S. LANDIS

JUST sixteen years ago the writer had the good fortune to see in operation at Niagara Falls the first large scale unit for the fixation of atmospheric nitrogen. This costly experiment of Bradley and Lovejoy did not prove the commercial success anticipated, but in its two years of operation it served to attract the attention of the world to the nitrate phase of the industry. The principles so well demonstrated at Niagara, when carried to Europe with its more favorable natural advantages and economic conditions, started a development that has commercially survived to the present time. Had Bradley and Lovejoy enjoyed the advantages of Norway, we might today find their names as prominent in the industry as Pauling and Schönherr, if not Birke-land and Eyde.

### THREE TYPES OF NITROGEN FIXATION PROCESSES

The fixation of nitrogen has developed along three divergent lines with many secondary outgrowths. The oldest process dated back to Cavendish, who in 1785 undoubtedly produced some nitric acid by passing the electric spark through air. Bradley and Lovejoy in 1901 attempted to do the same thing on a commercial scale and had their apparatus in operation in 1902. Just about the time the Niagara work was abandoned Birke-land began his experiments in Norway, using a somewhat different style furnace. Schönherr followed with his furnace, and still later Pauling. The product of all of these processes was nitric acid or derivatives of the same. Many others have since entered the field, but have made little progress in a commercial way.

A second school, and I am including here only those processes which have survived in one form or another, is that which concerned itself with the fixation of atmospheric nitrogen in the form of cyanides and cyanamides. Frank and Caro for many years attempted to produce cyanide through the direct fixation of atmospheric nitrogen. Commercially unsuccessful in this attempt, they, however, succeeded in a small way in producing cyanamide from atmospheric nitrogen and calcium carbide about 1900, or just prior to the nitric acid work of Bradley and Lovejoy. They did not, however, make much progress in the development of their process in the early days, and it was not until 1906 that a commercial installation followed. Later followed the conversion of cyanamide to ammonia, and quite recently the oxidation of this ammonia to nitric acid.

The third school following the production of ammonia synthetically, from its elements, nitrogen and hydrogen, is represented in the work of Haber and

\* (a) West Virginia Geological Survey, Bull. II, "Levels and Coal Analyses," 1911, p. 296.

\* A paper read before the American Electrochemical Society on Oct. 1, 1915.

carried out almost simultaneously with Birkeland's developments in Norway.

These three systems of fixation which have survived to the present time are none of them twenty years old and in fact essentially had no producing capacity even twelve years ago. Ten years will actually cover the commercial history of the industry.

#### THE STATISTICS OF NITROGEN PRODUCTION

Before the advent of the fixation processes, the world's requirements of nitrogen were met by the nitrate beds of Chile, the recovery of ammonia in the coking of coal and the production of illuminating gas and from various vegetable meals and animal by-products. We are going to consider only the chemical nitrogen product in our further discussion. According to the best available statistics, ten years ago, or in 1908, the world's production of nitrogen in the form of Chilean nitrate and of sulphate of ammonia was equivalent to only 503,000 short tons of nitrogen. The fertilizer industry was the larger consumer of this nitrogen, and since the capacity of the cultivated acreage of the world for absorption of this nitrogen was fifty or one hundred times the above production, there was ample incentive for the development of an air fixation process.

In 1914, at the outbreak of the European war, the producing rate of the world in short tons of chemical nitrogen, according to the best available statistics, is given in the following table:

| Material:                                | Nitrogen,<br>Short Tons |
|------------------------------------------|-------------------------|
| Nitrate of soda.....                     | 425,000                 |
| Sulphate of ammonia.....                 | 285,000                 |
| Arc process products.....                | 11,000                  |
| Cyanamide products.....                  | 31,000                  |
| Synthetic ammonia and miscellaneous..... | 12,000                  |
| Total—short tons nitrogen.....           | 764,000                 |

In 1919, say five years later, the producing capacity of the world, including the United States Government nitrate plants now under construction, is estimated to be as follows:

| Material:                                | Nitrogen,<br>Short Tons |
|------------------------------------------|-------------------------|
| Nitrate of soda.....                     | 520,000                 |
| Sulphate of ammonia.....                 | 350,000                 |
| Arc process products.....                | 15,000                  |
| Cyanamide products.....                  | 360,000                 |
| Synthetic ammonia and miscellaneous..... | 116,000                 |
| Total—short tons nitrogen.....           | 1,341,000               |

#### UNIFORM INCREASE IN PRODUCTION

An analysis of the production statistics of the world for ten years prior to the outbreak of the war shows a very uniform rate of increase. The curve is almost exactly a straight line. If we carry this rate of increase forward into the future it indicates a producing rate for 1919 of 1,330,000 short tons of nitrogen, or essentially the same as our figure given above for actual production, 1,341,000 tons. Such a system of analysis, it seems, is justified in view of the very uniform rate of increase noted for years prior to the war, and we are forced to the single conclusion that as relates to the world as a whole there has not been the great over-expansion of producing capacity most of us have believed. The available nitrogen supply expanded under the influence of the war only to the point any one would have predicted in the spring of 1914 from a study of its past statistics.

In this connection it might be here added that about

1911 the world's production of nitrogen began to catch up with market demands as limited by the comparatively unexpanded trade channels which had not kept up with the increase of production. Prices slumped as a result, reaching the lowest point in the history of the industry in 1914, and only the outbreak of the war with its insistent demands saved a portion of the industry from financial disaster.

It is a question if a problem is confronting the world's nitrogen industry at the close of the war. Undoubtedly the demand will drop off somewhat with the advent of peace, but with the anticipated high food prices continuing for some time afterward, this drop in nitrogen consumption should not be excessive. On the other hand, many plants erected under the war-time emergency are so located geographically and economically that operation after the emergency is past will be impossible. We may, therefore, expect a material reduction in producing capacity. That the decrease in demand and in production will be somewhat of the same order is at least a plausible assumption, and we see no real reason for altering our earlier conclusion as to the existence of a real primary problem, as concerns supply and demand.

#### READJUSTMENT OF PRICES AND MARKETS IS BOUND TO COME

Of secondary interest, there is bound to be much readjustment of prices, markets, distribution, etc., for the new plants are located in many cases in consumption centers formerly drawing from a distance for their supplies. Former importers may become exporters and new products must supplant older varieties of materials. Legislation may even play an important part in affecting consumption not alone of the nitrogen, but even of the specific variety. The influence of these phases, secondary in a sense to supply and demand, cannot be foretold. A recurrence of the 1914 condition may ultimately occur again, particularly as there has been no expansion of propaganda and educational methods and sales organizations since 1914.

In the case of the United States the statistics, however, partake of a very difficult character. In 1914 the United States possessed no commercial fixation plants; the consumption was as follows:

#### U. S. CONSUMPTION OF NITROGEN IN 1914

| Material:                                      | Nitrogen,<br>Short Tons |
|------------------------------------------------|-------------------------|
| Nitrate of soda (import).....                  | 94,300                  |
| Equivalent sulphate of ammonia (domestic)..... | 36,600                  |
| Equivalent sulphate of ammonia (import).....   | 17,800                  |
| Cyanamide products (import).....               | 5,400                   |
| Total—short tons nitrogen.....                 | 154,100                 |

#### UNITED STATES NITROGEN STATISTICS

It is extremely difficult to estimate for 1919 a similar consumption rate. I am, however, reproducing here some figures which are at least representative of the magnitude to which the industry has grown, having included the best information on anticipated outputs of coke ovens and on the new Government nitrate plants now under construction and which will be in operation very early in the spring:

#### ESTIMATED PRODUCTION RATE 1919, U. S.

| Material:                           | Nitrogen,<br>Short Tons |
|-------------------------------------|-------------------------|
| Nitrate of soda.....                | 300,000                 |
| Equivalent sulphate of ammonia..... | 100,000                 |
| Cyanamide products (import).....    | 13,000                  |
| Cyanamide products (domestic).....  | 88,000                  |
| Synthetic ammonia.....              | 10,000                  |
| Total—short tons nitrogen.....      | 509,000                 |

The producing rate in the early part of 1919 will, therefore, be approximately three times that at the outbreak of the war. Before the war half the chemical nitrogen entered into the fertilizer industry, which for a considerable period of time has shown an increase of only about 10 per cent from year to year. Assuming this increase, applied to the whole industry, would have continued for the duration of the war, it is hardly to be expected that the consuming capacity at the beginning of 1919 should exceed 225,000 tons of nitrogen per year had there been no war.

#### INDUSTRY FACES UNUSUAL PROBLEM

Judging from past history, our only guidance, we can expect at the close of the war a more or less disturbed state of affairs lasting over an indefinite time. We have no reason for assuming an enormously increased market for nitrogen to develop with peace, and in fact the chances are greatly in favor of a decline below the estimated 225,000 tons. With a production capacity of over 500,000 tons and a maximum consumption of less than half that tonnage, the industry in the States faces an unusual problem.

Importation of nitrate of soda makes up over half the available tonnage. Undoubtedly a material reduction of this import will follow peace, possibly sufficient to balance supplies and demands. There will always be some demand for nitrate of soda in agriculture and the oxidation of ammonia will make only slow headway in the already equipped and amortized chemical plants, so we cannot hope for a complete cessation of nitrate imports. Certain fixation plants erected as war emergency plants will undoubtedly close down with the declaration of peace, or at least suspend during a period of removal to more favorable peace market localities. Exportation of surplus production is not excluded from contemplation.

#### NITROGEN INDUSTRY MUST UNDERGO CHANGE

The nitrogen industry of the States must undergo a complete change we must all admit. This enforced change, I believe, need not seriously affect the great producing interests of this country, but the distribution agencies are certain to be influenced. The changes of methods and materials will affect the consumer. Out of the whole can come much good.

For example, prior to the war, agriculture consumed about 50 per cent of the chemical nitrogen in the whole country in the form of mixed fertilizers. The ingredients, mostly low in content of plant food and collected from many places, were assembled at the seaboard and compounded there. This low plant food content, varying from 12 to 20 per cent of the whole, means high cost of assembling, mixing, bagging and transportation per unit of plant food. By the time the fertilizer had been transported 200 to 300 miles inland and distributed under an expensive system of credit the nitrogen cost the farmer about double its wholesale price at the ports. As a result 85 per cent of the fertilizer consumed in the country was used in a narrow strip of territory near the coast, and the enormous acreage of Middle Western cultivated lands went unfertilized. The high cost of the dilute fertilizer when transported to these states made its use either impossible or at least unattractive to the farmer from the standpoint of profitable return.

The great cereal crop-growing regions must have cheaper nitrogen to make available the vast market they present.

Now, neither the producer of the raw materials nor the compounder of the mixed fertilizer was a profiteer. A careful study of the situation—and statistics are available in ample quantity—shows that neither profited to more than a very moderate return on his invested capital. The difficulty lies in the enormous friction losses in handling a material averaging only between 12 and 20 per cent of valuable plant food and 80 to 88 per cent inert material. The labor, bags, freight and haulage applied to the inert material are lost. If they could be eliminated the cost of fertilizer could be reduced without either the producer of the raw materials or the compounder and distributor of the same suffering. With reduced cost to the farmer and more general distribution the cost of credits will be lowered. Half the price paid by the farmer went to the wholesaler of the raw materials and the other half for distribution. As this second half is largely proportional to the bulk handled, any means of reducing the inert material content should result in a lowering of these costs of mixing, bagging and distributing. The solution of the problem of a lowered cost of fertilizer is therefore logically one involving the production of a more concentrated material. And following the lowered cost will come the newer and larger markets with increased demand.

#### MUST FACE THE FACTS

The nitrogen industry of the United States, if it is to market its great production at the close of the war, must face these facts and be prepared to meet the issue. One of the youthful fixation processes has appreciated the situation and prepared itself through development of a concentrated fertilizer containing some 65 per cent plant food, more than four times as concentrated as an average mixed fertilizer. The cost of handling, mixing, bagging, freight and haulage will be cut in equal proportion to the concentration and it will be enabled to reach hitherto inaccessible markets, miles beyond the limit of the present dilute materials. The new fertilizer awaits only the close of the war and release of the ammonia supplies to enter the field. Crop tests have been carried out for some four to five years to show the value of nitrogen.

When fertilizer can be profitably put into the great Middle West the consumption will be enormous. Our apparently largely increased nitrogen production will not suffice to meet the demand. It would take the stimulating effect of several wars to build sufficient fixation plants to over-produce in such a market.

Thus the ten-year-old fixation industry with its freedom of action, absence of prejudice and broad appreciation of fundamental condition has not only come to the assistance of the Government in the war emergency, but has prepared itself to meet what might have been a serious national problem with the advent of peace. A closing of the plants with the world's shortage of food stocks is unthinkable, and yet such would appear on the face of statistics to have been the outcome had the problem not been attacked from its fundamentals. At least some of us do not look into the future with fear in spite of the figures.

## Book Reviews

A MANUAL OF CHEMICAL NOMOGRAPHY. By Horace G. Deeming, Ph.D. The University Press, Champaign, Illinois.

In this small pamphlet we have a most satisfactory practical treatment of the general method of graphical calculation, in its broadest sense, as applied to chemical problems of both scientific and industrial interest. That such methods in very many fields are of the greatest possible importance is not to be doubted; and the chemical profession owes a debt of gratitude to Dr. Deeming, not only for his general and excellent presentation of past work, but more especially for the new, original developments due entirely to him. This book, together with the accessories necessary for the practical application of the principles of the subject, which are now available, makes it possible for the first time for all chemists to employ this exceedingly useful method in their various calculations. And all chemists should consider it their duty to examine the book in order to see just what aid it can offer them in solving their problems, especially those which have more or less a routine nature.

CHEMICAL COMBINATION AMONG METALS, by Dr. Michele Giau and Dr. Clara Giau-Lollini. 341 pages. Price \$4.50 net. Philadelphia, P. Blackiston's Son & Co.

This book, which was awarded the prize of the Cagnola Foundation by the Royal Lombardy Institute of Science and Literature, has been rendered into very graceful English by Gilbert W. Robinson. It would be very noteworthy merely as a compilation presenting systematically the known binary equilibrium diagrams which give evidence of the occurrence of intermetallic compounds. Since the common conception of valency throws no light upon the formation of such entities, the authors make a main division of their subject into homopolar and heteropolar compounds, following Abegg. Thus, intermolecular forces are "polar" if they depend on the special affinity of the elements for electrons, while "unitary" forces lack this character. The valency of an element depends on the nature of the other elements with which it combines. Elements of distinct series in the Periodic System are heteropolar, while neighboring elements are homopolar. The greatest number of intermetallic compounds result from unitary forces and only in comparatively few cases are heteropolar compounds formed.

In another important chapter the authors outline what is known from systematic investigations of various physical properties of alloy series, such as conductivity, hardness, density and so on, pointing out that such studies are extremely important in reinforcing the evidence given by thermal analysis. Compounds are indicated by actual or submerged maxima on the liquidus; these compounds produce corresponding discontinuities or "singular points" on the curves representing a physical property plotted against composition.

The eminent Russian, Kurnakoff, has done much work in correlating thermak and electrical phenomena, and his work is referred to repeatedly by the authors. He has shown that some equilibrium diagrams exhibit thermal maxima which do not correspond to rational atomic proportions, while the curves for physical properties do not exhibit the expected discontinuities. Thus, there is much thermal evidence of a compound Bi<sub>2</sub>Tl, while fusion curves and electrical conductivity measurements have demonstrated the existence of a gamma phase between 55 and 65 atonic per cent bismuth—that is, in the same region as the hypothetical compound. This phase exists perfectly independently, but cannot be fitted into any of Roozeboom's types for solid solutions. Further, microscopic examination shows that it undoubtedly possesses the characteristics of a chemical compound. Such facts as these lend support to one of the most important conceptions of recent years—that there exist compounds of variable composition or "chemical individuals," defined by Wald as phases, which in a series

of equilibrium changes possess a notably constant composition.

While, as can be presumed, this book is largely a most useful compilation from a multitude of authorities, the authors present the results of some original, trail-blazing investigations showing that intermetallic compounds generally dissociate upon melting. They studied the lowering of the freezing point of such compounds by the addition of a metal which did not form solid solutions or new compounds, and their conclusions are based upon Van't Hoff's well-known formulas showing the relations between depression and the number of molecules and ions in the liquid.

It is regrettable that such an excellent text should possess such a repellantly-colored binding. The clear typography is poorly matched by the sketchy, undraftsmanlike diagrams, evidently reproduced exactly from the Italian edition, and strangely enough, without captions. Several errors in printing the formulas may be easily noted, but it is indeed a rare book in English which can boast "letter-perfect" in this respect.

## Personal

MR. ERL V. DAVELER is now mill superintendent of the Butte & Superior Mining Co., at Butte, Mont.

DR. HAROLD S. DAVIS has been appointed to the research staff of the H. Koppers Co., Pittsburgh, Pa., one of the largest manufacturers and operators of by-product coke ovens, benzol and toluol plants. Dr. Davis will carry on his work at the Mellon Institute.

MR. FRANCIS N. FLYNN is assistant general superintendent of the Balbach Smelting & Refining Co., Newark, N. J.

MR. JOHN E. GALVAIN has been elected president of the Ohio Steel Foundry Company, Lima, Ohio. He has been operating vice-president since its organization in 1907 and has taken an active part in the organization, having designed and erected the Lima plant.

MR. C. C. GORDON, who is operating a custom smelter near Yauli, in Central Peru, is in the United States investigating chloridizing volatilization processes.

MR. C. J. HALL is now with the Copper Queen Reduction Works, Douglas, Ariz., having resigned his position with the Garfield Smelting Co., Garfield, Utah.

MR. E. C. HICKMAN is now assistant superintendent with the St. Joseph Lead Co., at Hercules, Mo. He was formerly with the American Smelting & Refining Co., Murray, Utah.

MR. EDWARD K. JUDD has resigned as managing editor of the Bulletin of the American Institute of Mining Engineers to take a position in the operating department of the American Metal Co., 61 Broadway, New York.

MR. WILLIAM M. KINNEY has been appointed general manager of the Portland Cement Association to succeed Mr. H. E. Hilt, resigned.

MR. OTTO KRESS, who has been connected with the U. S. Forest Products Laboratory, Madison, Wis., in charge of its research work on pulp and paper, is now with E. I. du Pont de Nemours & Co., Wilmington, Del., as director of the new technical dyestuff laboratory in the dyestuff sales department.

MR. JAMES M. McCLEAVE is now president of the Western Research Corporation, 514 Eighteenth Street, Denver, Colo.

MR. BYRON T. MOTTINGER announces that after Jan. 1, 1919, he will be associated as chief engineer and master mechanic with the Quaker City Rubber Co., Wissinoming, Philadelphia, Pa.

MR. A. IRA RENICK has resigned as mill superintendent for the Climax Molybdenum Company, and is now at Anaconda, Mont. Mr. Renick has been succeeded at Climax, Mont., by Mr. O. G. ANDERSON.

MR. FOREST RUTHERFORD, consulting metallurgical engineer, has returned to New York from Colorado.

MR. L. E. SCHUMACHER, who for the past eight years

has been chief inspector of the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has been promoted to works manager of the Krantz Manufacturing Co. of Brooklyn, N. Y., the latest subsidiary of the former company.

MR. E. GYBON SPILSBURY has been appointed to represent the American Institute of Mining Engineers at the Engineering Congress in Paris. The delegation from the United States, invited by the French Government, is composed of members of the four national engineering societies. These representatives sailed on Dec. 5 and expect to be away about six weeks.

---

## Obituary

---

MR. H. P. CORLISS, the discoverer of alpha-naphthalamine as a flotation agent, died of pneumonia at Ray, Ariz., on Nov. 16.

MR. EDWARD RANDOLPH, president of the Balbach Smelting and Refining Co., Newark, N. J., died suddenly in his office Oct. 11, 1918.

## Current Market Reports

### The Iron and Steel Market

Our last review noted that the thought was then rising that the War Industries Board would not indulge in further price fixing, the thought immediately after the signing of the armistice having been that price fixing would continue, even, perhaps, to the extent of fixing minimum prices so as to prevent a slump in the market. This "rising thought" has since become universal. The War Industries Board indicated that it would not fix prices on any material after the present quarter unless urged to do so, with presentation of cogent reasons, and the industry has come to the conclusion that it does not want prices to be fixed.

Market conditions and prospects can therefore be discussed on the basis that there will be no further price fixing by the War Industries Board. The common thought seems to have been, at least until very lately indeed, that such abandonment of price fixing would leave the iron and steel market altogether adrift, and the word "chaos" has even been used. Nothing of the sort. The iron and steel market is left in a very familiar condition indeed, the condition that obtained in the summer of 1900, the second quarter of 1903, the latter part of 1907, the latter part of 1910 and the summer of 1913. In all those cases there had previously been an active demand, the establishment of a relatively high level of prices with an absolutely steady market and full order books, while there was no further buying except for the filling of immediate and pressing wants. To-day the alignment is precisely the same, though of course each time such a situation arises the proportions of the items that make up the situation are somewhat different.

### PHILOSOPHY OF THE STEEL MARKET

The American iron and steel market may have a philosophy of its own. The writer does not know, not being conversant with other philosophies, but the philosophy of the steel market is perfectly clear, and can either be read from plainly recorded history or can be developed from recognized principles, according to whether one prefers the inductive or comparative method of reaching conclusions.

As to the principles involved: First, the iron and steel producers have a large tonnage of business on their books. Some was entered during the period of price control, and therefore at Government prices. Some was entered before the period of price control, at various prices. Speaking in averages, prices before March 1, 1917, were below the Government levels later established, while prices afterward, to the time of Government control, were at higher than Government levels. There is very little tonnage at less than Government prices. Second, there is buying now, by those who want material at once and who do not balk at price because they can turn the material over at once. Third, there is no forward or "investment" buying and no inquiry along that line. Such buyers have no price in mind at which they would take hold if they were quoted the price. Obviously the attractive course for the individual seller would be to maintain existing prices, which are well known and understood. Those who would buy at all would buy more readily at these prices than in an uncertain and declining market. Those who have material due them on contract would much more readily accept it at the contract price than if the market were declining. Nothing is lost and much is gained.

The records are clear that this is precisely what iron and steel producers have done in the past in similar circumstances. In all the five cases cited there was the individual incentive to hold to prices. There was always more or less "team work," in the earlier times helped somewhat by pools and associations and after the collapse of demand in 1907 by the "Gary dinner" system. Those were merely helps, however, the individual incentive being naturally present.

### WHEN WILL PRICES DECLINE?

The immediate question, therefore, is not how far prices will decline but how long it will be before they begin to decline. With prices so high it is not the presence of active demand, but its absence, that operates to maintain the existing price level. There is no incentive to cut, while there is an incentive not to cut, but to nurse the existing contract tonnage on books and effect the largest possible deliveries against it. Some contracts are firmer, legally, than others, but the amounts of money are so large that many buyers would be ruined by taking material at contract prices if a slump in the market made it that their competitors could buy at much less. Of course there may be quiet shading by some producers, but unless pronounced it can be ignored. There was more or less shading throughout 1908, very quiet, and the Gary price maintenance was not formally abandoned until Feb. 20, 1909. When the dwindling of the volume of contract business remaining and the development of a buying disposition needing to be encouraged progress far enough that the balance is tipped and the incentive to cut becomes greater than the incentive not to cut, the market breaks. That break may occur a few weeks after Jan. 1, 1919, or a few months after that date. It will be the most remarkable accident that ever befell the market if it occurs in January. Of course there is a bare possibility of a new and lower level of prices being put out, perhaps under Steel Corporation leadership, in hope of the market being stabilized upon it, but that is extremely improbable.

As indicated in last report, buyers may be divided into classes, according to the period of time in which they are able to reconvert their purchases into cash. It may be estimated roughly that in the steel market as constituted before the war fully one-half the buying was of material for construction purposes intended to return the capital in a period of ten years or more. There can be no such buying at present and the banked up demand of those who can turn over their purchase quickly cannot long keep the industry operating at capacity.

#### BUYER REQUIRES STABLE MARKETS

Obviously the investment buyer is not simply waiting for lower iron and steel prices. If that were all, the producers could easily reach an understanding with him. He wants to know something about what is going to occur in the world, and in particular he requires a stable market for labor and the other materials he must buy, for when steel is bought in the investment sense it requires labor and materials to put it into employment. Sometimes, as in the case of an office building, the steel itself is but a small part of the total cost. In many cases the investment buyer would refuse steel as a gift, if he were required to utilize it at once by buying the other materials and employing the labor necessary to do so.

The delay in the development of investment buying was of course entirely to be expected. In its policy of allowing the mills to continue at work for a time on war steel orders, when the material will hardly be needed, the Government did not contemplate continuing this expenditure until the investment buyer should appear. The policy is an altogether temporary one, to relieve the shock, and the cancellations of orders in process of being filled have been heavier than has been generally reported.

Apart from this necessary delay before regular investment buying is ready to take hold there are two unfortunate circumstances as to steel demand. The first is that the Emergency Fleet Corporation has a large excess of hulls waiting for equipment, launchings having exceeded vessel completions by more than a million tons deadweight, and there is also an accumulated surplus of more than a million tons of plates, represented by the mill shipments minus the plates necessarily in transit or process of fabrication or already entered into hulls. These excesses were an expensive but justifiable factor of safety at one time, but now the program involves greatly reduced plate shipments for account of the Fleet Corporation until a balance is produced. The second unfortunate circumstance is that the railroad problem is in such shape that there is no buyer who can take hold in anything like a free way.

#### RAILROADS IN A QUANDARY

Congress must decide what is to be done with the railroads. The Railroad Administration cannot buy freely, for the roads may be returned to their former owners, who would object to almost any prices paid for steel, as indeed they have objected to prices paid during the war, asking the Government to stand the difference between the price and the post-war value. The individual railroads cannot buy, as they have not the incentive to build up the properties and do not know whether they can afford to buy. The railroads have hitherto

been the steel industry's best single customer, but no buying of real magnitude can occur until something like a decision has been reached as to who is eventually to own and operate the railroads.

Beyond question there will eventually be a heavy demand for iron and steel, chiefly in the great American market rather than for export, and the demand may continue for several years, but there is uncertainty when it will develop. As in geology, the time element is the most uncertain. So it can be predicted that there will be maintenance of the existing prices and declining mill activity, then a break in prices, buying by investors, a rising market again and a sustained period of demand.

#### The Non-Ferrous Metal Market

*Saturday, Dec. 7.*—In general fair stocks of the non-ferrous metals are being held by the consumers, who are not inclined to buy more and feel that by not forcing the market they will be able to replace their stocks more economically later.

*Aluminum.*—The Government prices on ingots 98 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots; \$662 down to 15-ton lots; and \$666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

*Antimony.*—The volume of sales is not large even at prices from 8½c. to 8¾c. per pound.

*Copper.*—The price of \$520 per ton for carload lots and 27½c. per pound for small quantities was continued for another period at the conference held on Oct. 25 at Washington. Production declined 3400 tons during November due to the hesitating market conditions. Casting copper is being quoted at 23c. per pound.

|                                 |     |        |          |
|---------------------------------|-----|--------|----------|
| Copper sheets, hot rolled.....  | lb. | \$0.36 | —\$0.37½ |
| Copper sheets, cold rolled..... | lb. | .37    | — .38½   |
| Copper bottoms.....             | lb. | .44    | — .45½   |
| Copper rods.....                | lb. | .36    | — .37    |
| Copper wire.....                | lb. | .29½   | — .30    |
| High brass wire.....            | lb. | .28½   | — .29½   |
| High brass sheets.....          | lb. | .28    | — .29    |
| High brass rods.....            | lb. | .28½   | — .29½   |
| Low brass wire.....             | lb. | .32½   | — .34    |
| Low brass sheets.....           | lb. | .32½   | — .34    |
| Brazed brass rods.....          | lb. | .33½   | — .35    |
| Brazed brass tubing.....        | lb. | .33    | — .34    |
| Brazed bronze tubing.....       | lb. | .42½   | — .44½   |
| Seamless copper tubing.....     | lb. | .41    | — .42    |
| Seamless bronze tubing.....     | lb. | .45    | — .46    |
| Seamless brass tubing.....      | lb. | .37½   | — .39½   |
| Bronze (bronze) powder.....     | lb. | 1.00   | — 1.15   |

*Lead.*—Lead has been the first of the major military metals to decline. Transactions are not large and prices at East St. Louis are \$135 per ton and 7.05c. per pound in New York.

*Silver.*—Due to the flow of silver to Asia in payment for munitions and the greatly increasing industrial consumption in photography, motion picture reels and silverware, there is a shortage of silver even at the present government price of \$1.01½ per ounce.

*Tin.*—The Tin Committee of the American Iron and Steel Institute has not yet announced the official price on tin. No doubt an understanding will have to be had with the producers before a final statement can be made public and as they are all in distant foreign countries, considerable time will elapse in intercommunication, with the added possibilities that prices will not be legally fixed but adjusted by economic conditions as to demand by that time. The market is dull at a price of 72½c. per pound.

*Tungsten.*—The buyers of tungsten are decidedly cautious, though there is not likely to be any unlooked-for changes. Prices are nominal, scheelite bringing \$25, wolframite, \$20 to \$21, with no sales of low grade reported.

*Zinc.*—The spelter market continues to be on a firm basis, being little affected by the present transition period. Prime spot, New York, is \$172; East St. Louis, \$165 per ton; East St. Louis, December delivery, \$164; January, \$160; February, \$158, and March, \$157 per ton. Zinc dust, 13½c. to 16c. Sheet zinc, 15c. lb.

## OTHER METALS

|                 |        |               |
|-----------------|--------|---------------|
| Lithium .....   | lb.    | \$3.50—\$3.65 |
| Cadmium .....   | lb.    | 1.50 .....    |
| Cobalt .....    | lb.    | 2.50—3.50     |
| Magnesium ..... | lb.    | 1.75—2.10     |
| Mercury .....   | 75 lb. | 120.00 .....  |
| Mercury .....   | lb.    | 1.95 .....    |
| Nickel .....    | lb.    | 1.40—1.43     |
| Tungsten .....  | lb.    | 34.00 .....   |
| Iridium .....   | oz.    | 175.00 .....  |
| Palladium ..... | oz.    | 135.00 .....  |
| Platinum .....  | oz.    | 108.00 .....  |

## The Chemical Market

**HEAVY CHEMICALS:**—At the present time most chemicals, with only a few exceptions, show very little movement of character. Buyers in the general trade are not disposed to purchase ahead any quantities of material, but are seemingly confining their attentions to immediate needs, which therefore tends to keep business quiet and of a routine nature. While caustic soda has had a flurry of activity, this condition existed only temporarily, with the final disposition on the part of buyers to await developments of shipping space. It is evident that the necessity of cargo space is having a tendency to curtail the volume of trading and whatever stock may be accumulated will be taken up by export demand when this situation becomes easier. Soda ash during the interval has been considerably neglected while the position of bleaching powder has developed more firmly on the recent advance.

**Bleaching Powder:**—The item has had a varied experience; while prices were on the decline for a period, a firming up set in, particularly for material in export drums, which are none too liberal in supply, while trading for domestic drums is somewhat easier. The product in export drums is quoted at 3½c. to 3¾c. works, while that in domestic drums is offered at 2½c. to 2¾c.

**Soda Ash:**—There has been no particular buying interest evident in any of the items that come under this heading and cheap offerings have frequently appeared on the market. Bag material was offered as low as \$2.25 per hundred pounds ex dock, while material from the warehouse was available at \$2.30 to \$2.35, though this price could possibly be shaded on a firm bid. Barrels were subject to no important movement and were held at a variation of prices ranging from \$2.65 to \$2.80 per hundred pounds, though in Chicago offerings were made as low as \$2.55. Double bags from western shipping points were quoted at from \$2.70 to \$2.90, but no particular buying interest was in evidence.

**Caustic Soda:**—The recent announcement of the war trade board, that all restrictions relative to this item have been lifted and that licenses would be granted for any destination, has had a very noticeable effect and prices were advanced from \$3.95 to \$4.20. However, a slackening up set in when the question of cargo space arose and a firm but quiet market has since prevailed. Material from the warehouse was quoted at \$4.20 with \$4.30 being the asking price for F. A. S. delivery. The ground caustic is subject to no important call and is offered at 5c. per pound.

**Potash:**—The lack of buying interest has brought about declines in prices, throughout, and weak holders are seemingly playing havoc with the market, considering the cheap offerings made. The U.S.P. product declined from \$1.75 and \$1.85 per pound to \$1.60 and \$1.70 with virtually no inquiry for the technical product that is quoted at \$1.40 to \$1.50.

**Sodium Acetate:**—Comparatively little interest has been taken lately in this product and the only activity in the market is created by the frequent offerings made. Quotation for carload lots are made at 21c. to 22c. while lesser quantities are offered at 23c. to 25c.

**Zinc Oxide:**—The only interest at the moment is for export purposes while in the local market quietness prevails. Standard brands are being quoted at from 13½c. to 14c.

**Bicarbonate of Soda:**—The firm situation that has been in evidence for this item still prevails, and prices are continued at their former levels. Barrels from the works are offered at 3½c. per pound, while material on the spot is quoted at 3½c. to 3¾c. with the price of keg material being a fraction of a penny higher.

**Nitrate of Soda:**—Restrictions relative to this material have been rescinded and orders are now being accepted for the product, but the entire situation at the moment is by no means easy; however, it is the impression that in January matters will be definitely changed. November prices are \$4.40 ex dock and \$4.52½ ex dock for the 95% and the 96% respectively. The statistical position is as follows:

|                      | PRODUCTION (IN TONS) |           |           |
|----------------------|----------------------|-----------|-----------|
|                      | 1918                 | 1917      | 1916      |
| In October .....     | 239,600              | 253,400   | 235,000   |
| For ten months ..... | 2,317,500            | 2,419,700 | 2,331,100 |

|                              | Shipments from the West Coast for October<br>(as cable) |         |         |
|------------------------------|---------------------------------------------------------|---------|---------|
|                              | 1918                                                    | 1917    | 1916    |
| To Europe, tons .....        | 60,000                                                  | 96,100  | 146,100 |
| To United States, tons ..... | 254,750                                                 | 147,700 | 88,700  |
| To other parts, tons .....   | 11,600                                                  | 41,700  | 51,000  |

|                              | Shipments from Jan. 1 to Oct. 1 |           |           |
|------------------------------|---------------------------------|-----------|-----------|
|                              | 1918                            | 1917      | 1916      |
| To Europe, tons .....        | 806,600                         | 893,700   | 1,205,150 |
| To United States, tons ..... | 1,573,050                       | 1,218,400 | 987,800   |
| To other parts, tons .....   | 95,200                          | 152,600   | 211,950   |

**COAL TAR PRODUCTS:**—With a few exceptions there were no new developments in this market and despite the quietness that has prevailed prices were generally firmly maintained, except in the crude products, of which some have been subject to a decline, particularly toluol, which went down with a swoop, and cheap offerings appeared in the resale market. Many of the intermediates are still in scant supply, which tends to maintain prices, but the consuming trade is not so pressing as to even affect this situation. It appears to be the general attitude on the part of buyers to await developments, and they are inclined to believe the recent occurrences will bring about a reduction in prices. Benzol and phenol have not changed in prices and the governing conditions in this market remain as previously indicated.

**H. Acid:**—The item is one that is now more free in supply, but this condition has apparently been brought about by the lack of buying interest. However, no price concessions are made to encourage business and the situation remains firm.

**Phenol:**—The market has undergone no reportable change; large producers maintain their former prices; however, some weak holders are offering in the resale market 2c. and 3c. below manufacturers' quotations.

**Benzol:**—Quietness prevails in this market and the only movement at the moment is of a routine nature with no desire on the part of purchasers to buy up a surplus stock. Quotations for the commodity in tank cars are subject to no change, which also applies to drum material.

**Paraphenylenediamine:**—The usual trading that is in evidence for this product is reported to be passing, but otherwise no particular interest is noted. There are various grades of the material, therefore a wide range of prices is heard.

**Diphenylamine:**—Spot material is now more liberal and a rather steady volume of business is evident. Otherwise no material change is noted, with prices being firmly maintained.

**Alpha Naphthol:**—Users of this product appear to have eased up buying and stocks are supposed to have accumulated, but producers firmly maintain their prices for both the crude and refined products.

**Aniline Oil:**—While no surface stocks are reported in any one direction, the lack of buying interest has seemingly had some effect on the market and in some instances prices have declined 1c. to 2c.

**Aniline Salts:**—Stocks of this product are more liberal for immediate shipment, but the item appears to be neglected, although dealers up to the present writing have not altered their previous quotations.

**Benzidine:**—Locally there is no important interest displayed in the item, although a fair volume of business is passing for the base product, for export purposes, while the sulphate is lagging. Neither the base or sulphate are subject to any price changes, previous quotations being continued.

## General Chemicals

## WHOLESALE PRICES IN NEW YORK MARKET DEC. 6, 1918

|                                                   |         |        |               |        |

| Alcohol, denatured, 180 proof                     | gal.    | 69     | —             | 69     |
| Alum, ammonium lump                               | lb.     | 07 1/2 | —             | 08 1/2 |
| Alum, chrome ammonium                             | lb.     | 18     | —             | 19     |
| Alum, chrome potassium                            | lb.     | 20     | —             | 22     |
| Alum, chrome sodium                               | lb.     | 12 1/2 | —             | 13     |
| Alum, potash lump                                 | lb.     | 09 1/2 | —             | 10     |
| Aluminum sulphate, technical                      | lb.     | 02     | —             | 02 1/2 |
| Aluminum sulphate, iron free                      | lb.     | 03 1/2 | —             | 04     |
| Ammonia, anhydrous, 26 deg., carbonyls            | lb.     | 08 1/2 | —             | 09     |
| Ammonia, anhydrous                                | lb.     | —      | Nominal       | —      |
| Ammonium carbonate                                | lb.     | 12     | —             | 13     |
| Ammonium nitrate                                  | lb.     | —      | (Fixed Price) | 15     |
| Ammonium sulphate domestic                        | lb.     | 07 1/2 | —             | 08     |
| Amyl acetate                                      | gal.    | 5 30   | —             | 5 35   |
| Arsenic, white                                    | lb.     | 09 1/2 | —             | 10     |
| Arsenic, red                                      | lb.     | 65     | —             | 73     |
| Barium carbonate, 99 per cent                     | ton     | 80 00  | —             | 90 00  |
| Barium carbonate, 97-98 per cent                  | ton     | 65 00  | —             | 67 00  |
| Barium chloride                                   | ton     | 70 00  | —             | 80 00  |
| Barium sulphate (Blanc Fixe, Dry)                 | ton     | 04 1/2 | —             | 05     |
| Barium nitrate                                    | lb.     | 12     | —             | 13     |
| Barium peroxide                                   | lb.     | 30     | —             | 32     |
| Bleaching powder, 35 per cent chlorine            | lb.     | 03     | —             | 03 1/2 |
| Borax, crystals, sacks                            | ton     | 08 1/2 | —             | 09     |
| Bromine, crude                                    | ton     | 65 00  | —             | 70 00  |
| Bromine, technical                                | lb.     | 75     | —             | 85     |
| Calcium acetate, crude                            | lb.     | 04     | —             | 05     |
| Calcium carbide                                   | lb.     | 15     | —             | 17     |
| Calcium chloride, 70-75 per cent, fused, lump     | ton     | 22 00  | —             | 24 00  |
| Calcium peroxide                                  | lb.     | 1 50   | —             | 1 70   |
| Calcium phosphate                                 | lb.     | 22     | —             | 23     |
| Calcium sulphate, 98-99 per cent                  | lb.     | 09     | —             | 09 1/2 |
| Carbon bisulphide                                 | lb.     | 08     | —             | 09     |
| Carbon tetrachloride, drums                       | lb.     | 20     | —             | 25     |
| Carbonyl chloride (phosgene)                      | lb.     | 1 10   | —             | 1 50   |
| Caulic potash, 88-92 per cent                     | lb.     | 67     | —             | 72     |
| Caulic soda, 76 per cent                          | 100 lb. | 4 15   | —             | 4 25   |
| Chlorine, liquid                                  | lb.     | 13     | —             | 15     |
| Coal oil                                          | lb.     | 1 60   | —             | 1 65   |
| Cobalt oxide                                      | lb.     | 02 1/2 | —             | 02 1/2 |
| Copper                                            | lb.     | 30     | —             | 31     |
| Copper carbonate                                  | lb.     | 75     | —             | 78     |
| Copper cyanide                                    | lb.     | 09 1/2 | —             | 09 1/2 |
| Copper sulphate, 99 per cent, large crystals      | lb.     | 68     | —             | 73     |
| Cream of tartar, crystals                         | 100 lb. | 3 10   | —             | 3 40   |
| Epsom salt, bags, 1 1/2 P                         | 100 lb. | 1 60   | —             | 1 65   |
| Formaldehyd, 40 per cent                          | lb.     | 02 1/2 | —             | 03     |
| Glauber's salt                                    | lb.     | 63     | —             | 65     |
| Glycerine, bulk, C. P.                            | lb.     | 4 25   | —             | 4 30   |
| Iodine, resublimed                                | lb.     | 17     | —             | 17 1/2 |
| Iron oxide                                        | lb.     | 15     | —             | 18     |
| Lead acetate, white crystals                      | lb.     | 12     | —             | 14     |
| Lead arsenate (Paste)                             | lb.     | 15     | —             | 18     |
| Lead nitrate                                      | lb.     | —      | Nominal       | —      |
| Litharge, American                                | lb.     | 1 50   | —             | 2 05   |
| Lithium carbonate                                 | lb.     | 16     | —             | 17     |
| Magnesium carbonate, technical                    | lb.     | 14     | —             | 15     |
| Nickel salt, single                               | lb.     | 12     | —             | 13     |
| Nickel salt, double                               | lb.     | 10     | —             | 10     |
| Phosgene, sec. carbonyl chloride                  | lb.     | 1 17   | —             | 1 20   |
| Phosphorus, red                                   | lb.     | 1 20   | —             | 1 25   |
| Phosphorus, yellow                                | lb.     | 40     | —             | 45     |
| Potassium bicarbonate                             | lb.     | 1 25   | —             | 1 26   |
| Potassium bromide, granular                       | lb.     | 38     | —             | 40     |
| Potassium carbonate calcined, 85-90 per cent      | lb.     | 38     | —             | 40     |
| Potassium chlorate, crystals                      | lb.     | 60     | —             | 70     |
| Potassium cyanide, 98-99 per cent                 | lb.     | 3 75   | —             | 3 80   |
| Potassium iodide                                  | ton     | 300 00 | —             | 350 00 |
| Potassium nitrate, 80-85 p. c. basis of 80 p. c.  | ton     | 1 50   | —             | 1 75   |
| Potassium permanganate, U. S. P.                  | lb.     | 2 30   | —             | 2 50   |
| Potassium prussiate, yellow                       | lb.     | 88     | —             | 95     |
| Potassium sulphate, 90-95 p. c. basis of 90 p. c. | ton     | 47     | —             | 48     |
| Rochelle salts                                    | lb.     | 23 1/2 | —             | 24     |
| Salammoniac, grav. gran.                          | 100 lb. | 22     | —             | 1 65   |
| Salammoniac, white gran.                          | 100 lb. | 1 40   | —             | 1 65   |
| Salt soda                                         | 100 lb. | 1 00   | —             | 20 00  |
| Salt cake                                         | 100 lb. | 1 00   | —             | 20 00  |
| Silver cyanide, based on market price of silver   | lb.     | 6 1/2  | —             | 6 1/2  |
| Silver nitrate                                    | 100 lb. | 2 40   | —             | 2 40   |
| Soda ash, 58 per cent light, flat                 | 100 lb. | 3 40   | —             | 3 60   |
| Soda ash, 58 per cent, dense, flat                | 100 lb. | 3 40   | —             | 3 60   |
| Sodium acetate                                    | lb.     | —      | Nominal       | —      |
| Sodium bicarbonate, domestic                      | lb.     | 03 1/2 | —             | 04     |
| Sodium bicarbonate, English                       | lb.     | 18 1/2 | —             | 20     |
| Sodium bicarbonate, technical                     | lb.     | 12     | —             | 14     |
| Sodium bisulphite, p. w. d.                       | lb.     | 25     | —             | 25 1/2 |
| Sodium chlorate                                   | lb.     | 30     | —             | 30     |
| Sodium cyanide                                    | lb.     | 17     | —             | 18     |
| Sodium fluoborate, commercial                     | lb.     | 17     | —             | 18     |

|                                        |         |        |         |        |
|----------------------------------------|---------|--------|---------|--------|
| Sodium hyposulphate                    | lb.     | 3 10   | —       | 3 50   |
| Sodium molybdate, per lb. of Mo        | lb.     | 2 50   | —       | —      |
| Sodium nitrate, 95 per cent            | 100 lb. | 4 1/2  | —       | 5 06   |
| Sodium nitrite                         | lb.     | 27     | —       | 30     |
| Sodium peroxide                        | lb.     | 35     | —       | 45     |
| Sodium phosphate                       | lb.     | 34     | —       | 34 1/2 |
| Sodium prussiate, yellow               | lb.     | 03     | —       | 06     |
| Sodium silicate, liquid (60 deg.)      | lb.     | 04     | —       | 04     |
| Sodium sulphide, 30 per cent, crystals | lb.     | 04 1/2 | —       | 05 1/2 |
| Sodium sulphate, 98 per cent, fused    | 100 lb. | 08     | —       | 09     |
| Sodium sulphate                        | lb.     | 05 1/2 | —       | 06     |
| Strontian nitrate                      | lb.     | 25     | —       | 30     |
| Sulphur, chloride, drums               | lb.     | 07 1/2 | —       | 09     |
| Sulphur dioxide, liquid, in cylinders  | lb.     | 15     | —       | 40     |
| Sulphur, flowers, sublimed             | 100 lb. | 3 70   | —       | 4 30   |
| Sulphur, r. c. l.                      | 100 lb. | 3 70   | —       | 3 85   |
| Sulphur, crude                         | ton     | 65 00  | —       | 70 00  |
| Tin bichloride, 50 deg.                | lb.     | 28     | —       | 29     |
| Tin oxide                              | lb.     | —      | Nominal | —      |
| Zinc carbonate                         | lb.     | 18     | —       | 20     |
| Zinc chloride                          | lb.     | 15     | —       | 15 1/2 |
| Zinc cyanide                           | lb.     | —      | Nominal | —      |
| Zinc dust, 550 mesh                    | lb.     | 13 1/2 | —       | 14     |
| Zinc oxide, American process XX        | lb.     | 12     | —       | 14     |
| Zinc sulphate                          | lb.     | 04 1/2 | —       | 06 1/2 |

## Coal Tar Products (Crude)

|                                       |      |      |               |       |
|---------------------------------------|------|------|---------------|-------|
| Benzol, pure, water white             | gal. | 22   | —             | 27    |
| Benzol, 90 per cent                   | gal. | 25   | —             | —     |
| Toluol, in tanks                      | gal. | —    | (Fixed Price) | 1 50  |
| Toluol, for non-aqueous use, in drums | gal. | —    | (Fixed Price) | 1 50  |
| Xylol, pure, water white              | gal. | 45   | —             | 55    |
| Solvent naphtha, water white          | gal. | 18   | —             | 25    |
| Solvent naphtha, crude, heavy         | gal. | 12   | —             | 15    |
| Cresol, 25 per cent                   | gal. | 45   | —             | 55    |
| Dip. oil, 20 per cent                 | gal. | 40   | —             | 45    |
| Pitch, various grades                 | ton  | 8 00 | —             | 20 00 |
| Carbolic acid, crude, 95-97 per cent  | lb.  | 07   | —             | 10    |
| Carbolic acid, crude, 50 per cent     | lb.  | 60   | —             | 65    |
| Carbolic acid, crude, 25 per cent     | lb.  | 35   | —             | 38    |
| Cresol, U. S. P.                      | lb.  | 19   | —             | 20    |

## Intermediates, Etc.

|                                |     |       |         |        |
|--------------------------------|-----|-------|---------|--------|
| Alpha naphthol, crude          | lb. | 1 00  | —       | 1 10   |
| Alpha naphthol, refined        | lb. | 1 50  | —       | 1 60   |
| Alpha naphthylamine            | lb. | 55    | —       | 60     |
| Aniline oil, drums extra       | lb. | 38    | —       | 39     |
| Aniline salts                  | lb. | 42    | —       | 43     |
| Anthracene, 80 per cent        | lb. | —     | Nominal | —      |
| Benzaldehyde (f. f. c.)        | lb. | 4 1/2 | —       | 4 50   |
| Benzidine, base                | lb. | 1 75  | —       | 1 85   |
| Benzidine, sulphate            | lb. | 1 40  | —       | 1 45   |
| Benzoic acid, U. S. P.         | lb. | 2 50  | —       | 2 75   |

| Chicago, motor       | gal. | 221 | 23  |
| Oklahoma, motor      | gal. | 211 | —   |
| San Francisco, motor | gal. | 201 | —   |

### Paraffine Waxes

|                             |     |     |     |
|-----------------------------|-----|-----|-----|
| Crude, 103 to 105 deg. m.pt | lb. | 081 | 09  |
| Crude, 118 to 120 deg. m.pt | lb. | 091 | 10  |
| Crude, 124 to 126 deg. m.pt | lb. | 10  | —   |
| Refined, 120 deg. m.pt      | lb. | 13  | —   |
| Refined, 128 deg. m.pt      | lb. | 14  | —   |
| Refined, 135 deg. m.pt      | lb. | 16  | 164 |
| Ozokerite, brown            | lb. | 75  | 80  |
| Ozokerite, green            | lb. | 85  | 90  |

### Lubricants

|                                             |      |    |    |
|---------------------------------------------|------|----|----|
| Black, reduced, 29 gravity, 25-30 cold test | gal. | 24 | 25 |
| Cylinder, light                             | gal. | 45 | 50 |
| Cylinder, dark                              | gal. | 39 | 43 |
| Paraffine, high viscosity                   | gal. | 40 | 41 |
| Paraffine, 0.903 sp. gr.                    | gal. | 36 | 38 |
| Paraffine, 0.885 sp. gr.                    | gal. | 26 | 28 |

### Flotation Oils

(Prices at New York unless otherwise stated)

|                                                     |      |    |    |
|-----------------------------------------------------|------|----|----|
| Pine oil, crude, f. n. b. Florida                   | gal. | 44 | —  |
| Pine oil, steam-distilled, sp. gr. 0.925-0.940      | gal. | 58 | 60 |
| Pine oil, destructively distilled                   | gal. | 58 | 60 |
| Pine-tar oil, sp. gr. 1.02-1.035                    | gal. | 35 | —  |
| Pine-tar oil, double refined, sp. gr. 0.965-0.990   | gal. | 37 | —  |
| Pine-tar oil, ref., light, sp. gr. 0.950, tank cars | gal. | 42 | —  |
| f.o.b. works                                        | gal. | 37 | —  |
| Pine-tar oil, ref., heavy, sp. gr. 1.025, tank cars | gal. | 28 | —  |
| f.o.b. works                                        | gal. | 32 | —  |
| Pine-tar oil, ref., tbin, sp. gr. 1.060-1.080       | gal. | 32 | —  |
| Turpentine, crude, sp. gr. 0.870-0.900              | gal. | 45 | —  |
| Hardwood oil, f.o.b. Michigan, sp. gr. 0.960-0.990  | gal. | 23 | —  |
| Hardwood oil, f.o.b. Michigan, sp. gr. 1.06-1.08    | gal. | 23 | —  |
| Wood creosote, ref., f.a.b. Florida                 | gal. | 31 | —  |

### Naval Stores

|                                          |              |       |       |
|------------------------------------------|--------------|-------|-------|
| Rosin A-E barrel                         | 280 lb.      | 15.25 | 15.60 |
| Rosin F-I                                | 280 lb.      | 15.60 | 16.00 |
| Rosin K-N                                | 280 lb.      | 16.00 | 16.00 |
| Rosin Q-W                                | 280 lb.      | 18.00 | 18.25 |
| Spirits of turpentine                    | gal.         | 71    | 73    |
| Wood turpentine, steam distilled         | gal.         | 62    | 65    |
| Wood turpentine, destructively distilled | gal.         | 58    | —     |
| Pitch                                    | bbl. 200 lb. | 8.00  | —     |
| Tar, kiln dried                          | 280 lb.      | 13.00 | 13.50 |
| Retort tar                               | 280 lb.      | 14.00 | 14.50 |
| Rosin oil, first run                     | gal.         | 80    | —     |
| Second run                               | gal.         | 83    | —     |
| Third run                                | gal.         | 88    | —     |
| Fourth run                               | gal.         | 98    | —     |

### Vegetable Oils

|                          |      |      |      |
|--------------------------|------|------|------|
| Castor oil               | lb.  | 33   | 34   |
| China wood oil           | lb.  | 24   | 26   |
| Cocunut oil              | lb.  | 16   | 21   |
| Corn oil                 | lb.  | 18   | —    |
| Coconutseed oil, crude   | lb.  | 20   | 22   |
| Linsed oil, raw, cars    | gal. | 1.81 | 1.86 |
| Palm                     | lb.  | 18   | 184  |
| Peanut oil, crude        | lb.  | 18   | 22   |
| Soya bean oil, Manchuria | lb.  | 17   | 183  |

### Glues

|                            |      |      |      |
|----------------------------|------|------|------|
| Extra white                | lb.  | 36   | 45   |
| Cabinet                    | lb.  | 31   | 40   |
| Brown foot stock           | lb.  | 22   | —    |
| Fish glue, 50-gal. barrels | gal. | 1.00 | 1.80 |

### Miscellaneous Materials

|                                     |         |         |       |
|-------------------------------------|---------|---------|-------|
| Barytes, roasted, white, foreign    | ton     | Nominal | —     |
| Barytes, roasted, white, domestic   | ton     | 33.00   | 36.00 |
| Beeswax, white, pure                | lb.     | 43      | 48    |
| Beeswax, unbleached                 | lb.     | 43      | 48    |
| Blanc fixe                          | lb.     | 051     | —     |
| Cassin                              | lb.     | 17      | 30    |
| Ceylon graphite                     | lb.     | 20      | 25    |
| Chalk, light, precipitated, English | lb.     | 041     | 06    |
| China clay, imported, lump          | ton     | 20.00   | 40.00 |
| China clay, domestic, lump          | ton     | 15.00   | 22.50 |
| Feldspar                            | ton     | 8.00    | 12.00 |
| Fluorspar, gravel, f.o.b. mine      | ton     | 28.00   | 40.00 |
| Fluorspar, washed, powdered         | ton     | 90.00   | —     |

Financial, Construction and Manufacturers' News

## Construction and Operation

### Arizona

**CHLORIDE**—The Schuykill Mining Co. will build a 500-ton concentration plant at its works, to provide for increased capacity.

**DUNCAN**—The Duncan Mining & Milling Co. will build an 80-ton concentration plant.

**DUNCAN**—Harold C. E. Spencer and associates will build a cyanide plant on property five miles from Steeple Rock.

**HUMBOLDT**—The Silver Belt Consolidated Mining Co. will build a reduction plant having a capacity of 100-tons per day. Colonel J. B. Dudley, manager.

**KINGMAN**—The Emerald Isle Copper Co. will build a new leaching plant at its local properties.

**MAYER**—The Orizaba Mining Co. will abandon the old steam surface plant and install distillate or gasoline plant. J. K. Turner, engineer in charge.

**PHOENIX**—The Mount Turnbull Copper Co. is in the market for new machinery and equipment for development. C. B. Barnhard, manager.

**WICKENBURG**—The Octave Mining Co. will build a 250-ton stamp mill at its local properties.

### Arkansas

**ASHLAND**—The Dixie Graphite Co., Jefferson Bank Building, Birmingham, Ala., will build a 20-ton mill and develop the local graphite properties. J. R. Malaney, manager.

**BATESVILLE**—The National Mangane Co. recently incorporated with a capital of \$100,000 will build a washing plant and plans the immediate installation of the necessary equipment for the development of approximately 230 acres of manganese properties. C. A. Enoche, president, and J. L. Elliott, vice-president.

**CUSHMAN**—The Enley Mining Co. will build a washing plant and is in the market for a log washer, jigs, belts, shafting, pulleys and mine equipment. Estimated cost, \$10,000. Clarence Edge, superintendent.

**DODD CITY**—The Salina Mining Co. will build a mill and is in the market for crushing and concentration machinery and mine equipment. Estimated cost, \$25,000. E. D. McGuire, superintendent.

**RUSH**—The Ozark Mining & Milling Co., Yellville, will build a 100-ton mill for the handling of zinc and lead ores. E. E. Scofield, manager.

### California

**MARE ISLAND**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of an oxy-acetylene plant here, to James L. McLaughlin, 234 Kearney St., San Francisco. Estimated cost, \$36,357. Noted Oct. 15.

**REDDING**—The Bully Hill Mining Co. will build a 150-ton flotation plant at its mine. Estimated cost, \$75,000.

### Colorado

**GARFIELD**—The Garfield Mining Co. will build a 50-ton mill at its properties here.

**SUNSHINE**—The Nil Desperandum Mines Co., Box 298, Boulder, will build an oil flotation plant to have a capacity of not less than 50 tons. Estimated cost, \$10,000. M. S. Brandt, president and general manager.

### Connecticut

**NEWINGTON**—Thomas F. Garvan & Co., Church St., Burnside, (Hartford P. O.), will rebuild its paper plant recently destroyed by fire entailing a loss of \$30,000.

## District of Columbia

**WASHINGTON**—The Bureau of Fisheries, Department of Commerce, received bids for the construction of a laboratory building at 7th and B Sts., from Boyle-Robertson Construction Co., 601 Evans Building, \$46,252; James L. Parsons, Jr., 332 Southern Building, \$48,462; A. C. Morse Construction Co., 916 New York Ave., \$48,110. Noted Nov. 30.

## Florida

**KEY WEST**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., plans to build a photo-laboratory here. Specification No. 3632. Estimated cost, \$7,000.

**TAMPA**—The Texas Co., 204 Gulf Bldg., Houston, has awarded the contract for the construction of an oil distributing plant, to G. A. Miller, 23 Petteway Blvd. Estimated cost, \$150,000.

**VERO**—The McVey Lindsey Co., Jacksonville, will build a syrup mill to have a grinding capacity of 60 tons per day. Estimated cost, \$15,000.

## Idaho

**BOISE**—The Sewer Department of the City Council is having studies made for the construction of a sewage disposal plant. C. C. Stevenson, engineer.

## Illinois

**CHICAGO**—The Chicago Starch Co., Throop and 27th Sts., has awarded the contract for the construction of a three story, 28 x 45 ft. factory, to Cameron Bros., 115 South Leavitt St.

**CHICAGO**—The Johns-Manville Co., Mayville, N. J., has purchased 225 acres of land near the town of Chicago, north of Chicago, and will build a plant for the manufacture of asbestos and magnesite. Estimated cost, \$5,000,000.

**CHICAGO**—The La Salle Steel Co., 2243 South La Salle St., has awarded the contract for the construction of two factory additions on 12th St. and 54th Ave., to Brolne & Nolan, 8 South Dearborn St. Estimated cost, \$18,000.

**CHICAGO**—D. A. Stewart & Co., 352 East Illinois St., will build a one story, 100 x 100 ft. factory on 31st St. and Kedzie Ave., for the manufacture of lubricating oil. Estimated cost, \$25,000. R. T. Newberry, 108 South La Salle St., architect.

**CHICAGO**—Swift & Co., U. S. Yards, will build an addition to its soap factory. Estimated cost, \$75,000. C. H. Kane, c/o owner, architect.

**CHICAGO**—Swift & Co., U. S. Yards, has awarded the contract for the construction of a three story, 200 x 300 ft. fertilizer plant to the Wieboldt Construction Co., 1524 West Van Buren St. Estimated cost, \$550,000.

**CHICAGO**—Wilson & Co., U. S. Yards, will build a three story, 33 x 129 ft. animal oil refinery building. Estimated cost, \$37,000. C. P. Barrett, c/o owner, architect.

**FAYVILLE**—The Actna Explosives Co., 120 Broadway, New York City, N. Y., will build an addition to its manufacturing plant here.

**GREAT LAKES**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of an addition to the water distribution system, to Daniel Hardin, 3139 Indiana Ave., Chicago. Estimated cost, \$125,000.

## Kentucky

**IRVINE**—The Mac-Lan Oil Co., Winchester, organized with J. W. McCulloch, Pres., Owensboro and J. H. McClurg, gen. mgr., Winchester, plans to develop oil land here.

**PADUCAH**—The Wallace Fluoropar Co., recently organized, will develop over 100 acres of local fluoropar properties and is in the market for machinery and equipment. C. P. Barrett, c/o owner, about 150 tons per day. N. R. Barbes, president.

## Maryland

**INDIAN HEAD**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of improvements to powder factory here, to Scott Brothers, Rome, N. Y. Estimated cost, \$38,605.

## Massachusetts

**BOSTON**—The Air Reduction Co., 120 Broadway, New York City, N. Y., has awarded the contract for the construction of a one story, 60 x 100 ft. plant, to the Austin Co., 217 Broadway, New York City, N. Y. Estimated cost, \$100,000.

**BOSTON**—The General Bond & Share Co., 30 Kilby St., capitalized at \$10,000, has taken over the plant of the Chapin Chemical Co., and will establish a large refinery on the property in the Seales Lake potash district.

**NORTH TRURO**—The East Harbor Fertilizer Co., 233 Bridge St., Springfield, will build a two story, 70 x 70 ft. fertilizer plant. Estimated cost, \$30,000.

**SHELBURNE FALLS**—The Mayhew Steel Products Co., 295 Broadway, New York City, N. Y., has awarded the contract for the construction of a one story, 60 x 100 ft. plant, to the Austin Co., 217 Broadway, New York City, N. Y. Estimated cost, \$115,000.

## Michigan

**DETROIT**—The Detroit Copper & Brass Rolling Mills, Clark Ave., has awarded the contract for the construction of an addition to its plant, to A. A. Albrecht, Penobscot Bldg. Estimated cost, \$400,000.

**DETROIT**—The Michigan Smelting and Refining Co., 1685 Joseph Campau Ave., will build a one story, steel cupola building, Albert Kahn, Marquette Building, architect.

**WYANDOTTE**—The city will construct a filter plant having a daily capacity of 6,000,000 gallons, composed of 6 filter units, 2 1/2 x 24 ft. of 1,000,000 gallons capacity each; 40 x 65 ft. and 37 x 73 ft. brick and steel filter house and head house; 2 coagulation basins of 64 x 34 ft. each; filtered water reservoir having capacity of 850,000 gallons; usual equipment of hydraulic valves and machinery; 100 x 100 ft. brick addition to pumping station. R. W. Pratt, 232 Jefferson Ave., Detroit, engineer.

## Minnesota

**WORTHINGTON**—The Commissioners of Nobles County have awarded the contract for the construction of a filter plant for the Southwestern Minnesota Sanitarium, to W. Danforth, Germania Life Bldg., St. Paul. Estimated cost, \$13,660.

## Missouri

**ST. LOUIS**—The Mallinckrodt Chemical Works, 2nd and Market Sts., St. Louis, has awarded the contract for the construction of a three story, 70 x 100 ft. plant for the manufacture of ether, to the A. H. Haeseler Building & Contracting Co., Wainwright Building. Estimated cost, \$65,000.

## Montana

**BASIN**—The Montana Consolidated Copper Co., 51 Wall St., New York City, N. Y., will remodel concentrator here for the treatment of mine ore. Properties in the market for rolls, jigs, tables, shafting, belting, motors, pumps, and possibly M. S. flotation machines, etc. Total estimated cost, \$200,000. E. P. J. Burgess, president.

## Nebraska

**OMAHA**—The city will build disposal plant for the Saddle Creek District. J. A. Bruce, city engineer.

## Nevada

**ELY**—The Shepherd Mining Co., operating tungsten properties in the White Pine Section, will build a 15-ton mill.

**LAS VEGAS**—T. Thorkildsen, Trade & Savings Building, Los Angeles, Cal., operating local manganese properties here, will double the capacity of plant which now averages about 200 tons per day.

## New Jersey

**NEWARK**—The F. W. De Voe & C. T. Reynolds Co., Inc., 223 New Jersey Railroad Ave., will build a 105 x 150 ft. plant for the manufacture of paper.

## New York

**BROOKLYN**—The George Washington Refining Co., 147 41st St., will build a

one story, 200 x 400 ft. refining plant. Austin Co., 217 Broadway, New York City, engineer R.

**BUFFALO**—The Donner Steel Co., Abbott Rd., will build three one story additions to its plant and a new addition to its plate mill. Estimated cost, \$27,000.

**DUNKIRK**—The Atlas Crucible Steel Co., Howard Ave., will build a one story addition to its plant.

**LONG ISLAND CITY**—The West Disintegrating Co., 411 5th Ave., New York City, has awarded the contract for the construction of a two story, 75 x 125 ft. factory on Bern St. and Jackson Ave., to Walter Bond, 12 Hallett St. Estimated cost, \$25,000.

**NEW YORK**—F. L. Dowling, president of Manhattan Borough, received bids Nov. 26 for furnishing and delivering liquid chlorine, from the Electro Bleach & Gas Co., 13 East 41st St., \$6120; A. Hoffman & Co., Providence, R. I., \$6900; furnishing and delivering sulphate of copper, from J. A. Miller, Grice, 39 Cordant St., \$2900; J. A. Miller, 4 West 34th St., \$2907; Knickerbocker Supply Co., 149 Church St., \$3045.

**POUGHKEEPSIE**—The Palline Aniline & Chemical Co. will build an addition to its plant for the manufacture of ferro-alloys. Estimated cost, \$40,000.

**MONROE**—The Bureau of Yards and Docks, Navy Department, Washington, D. C., will build a group of radio buildings here. Estimated cost, \$250,000.

## Ohio

**CARROLLTON**—The Robinson Clay Products Co. will build an addition to its plant.

**CASTALIA**—James D. Rhodes, Keystone Building, Pittsburgh, Penna., has been authorized by Judge Charles F. Orr, in the United States district court, to enter into an agreement with the Castalia Portland Cement Co. to experiment with the process by which he can wash iron dust from the kilns. It is understood that Mr. Rhodes, at his own expense, will erect a large experimental plant, adjoining the plant at Castalia. If the process is found to be of commercial value a \$1,000,000 plant will be erected and the process may be adopted in every cement-producing plant in the United States.

**CLEVELAND**—The Aluminum Castings Co., 2600 Harvard Ave., has awarded the contract for the construction of a one story, 50 x 200 ft. steel and concrete smelting finishing building, to the J. H. Chaney Co., Hippodrome Building. Estimated cost, \$100,000 and \$150,000 respectively.

**CLEVELAND**—The Ideal Bronze Co., 1265 East 53th St., will build a brick and concrete factory. Estimated cost, \$100,000.

**CLEVELAND**—The Kokomar Co., 455 Leader-News Building, will remodel its former brewery into a food manufacturing plant, where condensed butter, margarine, cereal, etc., will be made. The company is in the market for about \$100,000 worth of machinery.

**CLEVELAND**—The Reflex Ignition Co., 1705 Payne Ave., will build a two story, 50 x 75 ft. brick and concrete factory on West 106th St. Estimated cost, \$25,000.

**CLEVELAND**—The United States Copper Co., Guardian Bldg., will build a steel and concrete corner and brass mill. Estimated cost, \$100,000.

**RAVENNA**—The Oak Rubber Co. will soon award the contract for the construction of a three story concrete and steel factory. Estimated cost, \$100,000. Noted Nov. 30.

**SANDESKY**—The Libby Glass Co., South Hancock St., will rebuild its plant recently destroyed by fire.

## Pennsylvania

**BETHLEHEM**—The Air Reduction Co., 120 Broadway, New York City, N. Y., has awarded the contract for the construction of a three story, 120 x 200 ft. steel and concrete oxygen plant, to James Mitchell, Inc., 76 Montgomery St., Jersey City, N. J. Estimated cost, \$150,000.

**PHILADELPHIA**—The Ralfe Tannery will build additions to its plant.

**MAHANAY CITY**—The Hercules Powder Co., Du Pont Building, Wilmington, Del., will build a one story addition to its local plant.

## Tennessee

**COLUMBIA**—J. Ogden Armour Fertilizer Co. (branch of Armour & Co., Union Stock Yards, Chicago, Ill.), will build a

phosphate plant near the Century Mines and is in the market for phosphate dryers, washers and grinding plant, for the manufacture of fertilizer material. Total estimated cost, \$550,000.

## Texas

**FORT WORTH**—The Purety Serum Co., incorporated by John Kennedy, vice-president, and J. N. Huff, secretary, with \$150,000 capital has purchased a group of factory buildings here and will remodel same to manufacture serums and vaccines.

**GALENA**—The Petroleum Refining Co. will build additional units at its oil refinery.

**HOUSTON**—The Crown Oil Co. will build an oil refinery on Houston Ship Channel. Estimated cost between \$500,000 and \$1,000,000.
